Abstract

We study Bose-Einstein Condensation (BEC) in the Infinite-Range Hopping Bose-Hubbard model for repulsive on-site particle interaction in presence of ergodic random one-site potentials with different distributions. We show that the model is exactly soluble even if the on-site interaction is random. But in contrast to the non-random case [BD], we observe here new phenomena: instead of *enhancement* of BEC for perfect bosons, for constant on-site repulsion and discrete distributions of the single-site potential there is *suppression* of BEC at some *fractional* densities. We show that this suppression appears with increasing disorder. On the other hand, the BEC suppression at integer densities may disappear, if disorder increases. For a continuous distribution we prove that the BEC critical temperature decreases for small on-site repulsion while the BEC is suppressed at integer values of density for large repulsion. Again, the threshold for this repulsion gets higher, when disorder increases.

1 Introduction

Lattice Bose-gas models were invented as an alternative way to understand continuous interacting boson systems including liquid Helium, see [MM] and a very complete review [U]. But recent experiments with cold bosons in traps of three-dimensional optical lattice potentials show that lattice models are also relevant for describing the experimentally observed Mott *insulator-superfluid* (or condensate) phase transition [G-B]. In [BD] and then in [A-Y], this phenomenon was analyzed rigorously in the framework of the so-called *Bose-Hubbard* model.

The aim of the present paper is to study a *disordered* Bose-Hubbard model and in particular the influence of the *single-site potential* randomness on the Bose-Einstein condensate (BEC).

Notice that the first attempts to understand this influence go back to [KL1], [KL2] and [LS] for continuous Perfect Bose-Gases (PBG) in a random potential of *impurities*. For the rigorous solution of this problem see [L-Z]. One of the principal result of [L-Z] is that the randomness *enhances* the BEC. For example, the one-dimensional PBG has no BEC because of the high value of the one-particle density of states in the vicinity of the bottom of the spectrum above the ground state, making the integral for the critical particle density infinite. The presence of a non-negative homogeneous ergodic random potential modifies the one-particle density of states (due to the *Lifshitz tail*) in such a way that the integral for the critical density becomes finite. Hence, the one-dimensional PBG with random potential does manifest BEC. The nature of this BEC is close to what is known as the "*Bose-glass*" since it may be localized by the random potential [LZ]. This is of interest for experiments with liquid ^4He in random environments like Aerogel and Vycor glass, [F-F], [KT].

On the other hand, the nature and behaviour of the *lattice* BEC may be quite different. First of all, the lattice Laplacian and the Bose-Hubbard interaction produce a coexistence of the BEC (*superfluidity*) and the *Mott insulating phase* as well as domains of *incompressibility*, see e.g. [F-F], [K-C]. Adding disorder makes the corresponding models much more complicated. The physical arguments [F-F], [K-C] show that the randomness may *suppress* the BEC (superfluidity) as well as the Mott phase in favour of the localized *Bose-glass* phase, but this is very sensitive to the choice of the random distribution.

Since there are very few rigorous results about the BEC in disordered systems, we consider here a *single-site* random version of the lattice *Infinite-Range Hopping* (IRH) Bose-Hubbard model, which in non-random case has recently been studied in detail for all temperatures and chemical potentials in [BD].

This paper is organized as follows. In Section 2, we define the lattice Laplacian for finite- and infinite-range hopping and recall the results about BEC for the free lattice Bose-gas. We then introduce random single-site and on-set particle interaction potentials and state our main result about the existence of and an explicit formula for the pressure for the IRH Bose-Hubbard model with these type of randomness. We outline the proof of the main theorem using the approximating Hamiltonian method.

In Section 3 we consider the pressure for extremal cases of *hard-core* and *perfect* bosons. We show that they are the limits of the IRH Bose-Hubbard model pressure when the on-site particle interaction tends respectively to $+\infty$ and to 0.

In Section 4, we analyse the phase diagram in the case of a non-random on-site particle interaction and random single-site external potential. We distinguish a number of different cases. We start with *perfect* bosons and show that the randomness *enhances* BEC in this case, see Sect.4.1. This is no longer true for interacting bosons. We study in Sect.4.2 the phase diagram first for *Bernoulli* single-site potential and then for *trinomial* and *multinomial* discrete

distributions.

In the case of a Bernoulli distribution and hard-core bosons (infinite on-site repulsion) we show that in addition to the complete BEC *suppression* at extremal allowed densities $\rho = 0$ and $\rho = 1$ there is a new point $\rho = 1 - p$, where $p = \Pr\{\text{potential} \neq 0\}$. We prove that for finite on-site repulsion the suppression of BEC at *integer*, and also for *fractional* values of densities $\rho = n - p$, $n = 1, 2, \dots$ persists, if the Bernoulli potential amplitude is large enough. In fact we find that increasing the Bernoulli potential amplitude (disorder) decreases the critical BEC temperature in the vicinity of fractional values of densities but increases it for integer values of density. A similar phenomenon occurs also for *equiprobable* trinomial distributions, but now for densities $\rho = n/3$. Our numerical calculations demonstrate that it should be true for a general multinomial distribution.

For illustration of a continuous distribution we study a homogenous distribution with compact support. Then for hard-core bosons we prove that the complete BEC suppression occurs *only* at extremal allowed densities $\rho = 0$ and $\rho = 1$, with the trace of suppressions only at *integer* values of densities for a finite on-site repulsion. In particular we show that the critical BEC temperature gets *lower*, when one switches on disorder for (a small) on-site interaction, whereas it gets *higher* for perfect bosons. For large values of on-site interaction the picture is similar to the discrete distributions: increasing of disorder increases the critical BEC temperature in the vicinity of integer values of density but increases it for the complimentary values of density.

In Section 5 we summarize and discuss our results.

2 Model and Main Theorem

For simplicity we shall consider the Bose-Hubbard model only with *periodic boundary conditions*. So let $\Lambda := \{x \in \mathbb{Z}^d : -L_\alpha/2 \leq x_\alpha < L_\alpha/2, \alpha = 1, \dots, d\}$ be a bounded rectangular domain of the cubic lattice \mathbb{Z}^d wrapped onto a *torus*. Then the set $\Lambda^* := \{q_\alpha = 2\pi n/L_\alpha : n = 0, \pm 1, \pm 2, \dots \pm (L_\alpha/2 - 1), L_\alpha/2, \alpha = 1, 2, \dots, d\}$ is *dual* to Λ with respect to Fourier transformation on the domain $\Lambda = L_1 \times L_2 \times \dots \times L_d$ of volume $|\Lambda| = V$.

The standard *one-particle* Hilbert space for the set Λ can be taken as $\mathfrak{h}(\Lambda) := \mathbb{C}^\Lambda$ with the canonical basis $\{e_x\}_{x \in \Lambda}$, i.e. $e_x(y) = \delta_{x,y}$. Then for any element $u = \sum_{x \in \Lambda} u_x e_x \in \mathfrak{h}(\Lambda)$ the one-particle *kinetic-energy* (*hopping*) operator is defined by

$$(t_\Lambda u)(x) := \sum_{y \in \Lambda} t_{x,y}^\Lambda (u(x) - u(y)) = \sum_{y \in \Lambda} t_{x,y}^\Lambda (u_x - u_y), \quad (2.1)$$

where

$$t_{xy}^\Lambda = \frac{1}{V} \sum_{q \in \Lambda^*} \hat{t}_q e^{iq(x-y)}, \quad (2.2)$$

is the *periodic extension* in domain Λ of a *symmetric*, *translation invariant* and *positive-definite* matrix, i.e.

$$\hat{t}_q = \sum_{y \in \Lambda} t_{0,y}^\Lambda e^{iqy} \geq 0. \quad (2.3)$$

Notice that functions $\{(\hat{e}_q)(y) := e^{iqy}/\sqrt{V}\}_{q \in \Lambda^*}$ also form a basis in $\mathfrak{h}(\Lambda)$, i.e. for any $u \in \mathfrak{h}(\Lambda)$ one has $u = \sum_{q \in \Lambda^*} u_q \hat{e}_q$.

Let $\mathfrak{F}_B := \mathfrak{F}_B(\mathfrak{h}(\Lambda))$ be the *boson Fock space* over $\mathfrak{h}(\Lambda)$. For any $f \in \mathfrak{h}(\Lambda)$ we can associate in this space the creation and annihilation operators

$$a^*(f) := \sum_{y \in \Lambda} a^*(y) f(y) , \quad a(f) := \sum_{y \in \Lambda} a(y) f^*(y) . \quad (2.4)$$

Let a_x^* , a_x and \hat{a}_q^* , \hat{a}_q be the boson creation and annihilation operators corresponding respectively to the basis elements e_x and \hat{e}_q , satisfying the lattice *Canonical Commutation Relations*: $[a_x, a_y^*] = \delta_{x,y}$ and $[\hat{a}_q, \hat{a}_p^*] = \delta_{q,p}$. Then $n_x = a_x^* a_x$ is the *one-site* number operator, and

$$N_\Lambda := \sum_{x \in \Lambda} n_x = \sum_{q \in \Lambda^*} \hat{a}_q^* \hat{a}_q , \quad (2.5)$$

is the *total* number operator.

The second quantization of the hopping operator (2.1) in \mathfrak{F}_B gives the *free boson* Hamiltonian of the form

$$T_\Lambda := \sum_{x \in \Lambda} a_x^* (t_\Lambda a)_x = \frac{1}{2} \sum_{x,y \in \Lambda} t_{xy}^\Lambda (a_x^* - a_y^*) (a_x - a_y) = \sum_{q \in \Lambda^*} (\hat{t}_0 - \hat{t}_q) \hat{a}_q^* \hat{a}_q . \quad (2.6)$$

If hopping is allowed only between the *nearest neighbor* (n.n.) sites with equal probabilities, then $t_\Lambda = -\Delta$ corresponds to minus the *lattice Laplacian*, i.e.

$$t_{xy}^\Lambda = \sum_{\alpha=1}^d (\delta_{x+1_\alpha, y} + \delta_{x-1_\alpha, y}) , \quad (2.7)$$

where $(x \pm 1_\alpha)_\beta = x_\beta \pm \delta_{\alpha, \beta}$. In this case the one-particle hopping operator spectrum is

$$\epsilon(q) := (\hat{t}_0 - \hat{t}_q) = \sum_{\alpha=1}^d 4 \sin^2(q_\alpha/2) \geq 0 , \quad q \in \Lambda^* , \quad (2.8)$$

with eigenfunctions $\{\hat{e}_q\}_{q \in \Lambda^*}$.

It is known that the lattice free Bose-gas (2.6) with *n.n.* hopping manifests the *zero-mode* BEC when $d > 2$, since the spectral density of states $\mathcal{N}_d(d\epsilon)$ corresponding to (2.7) is small enough to make the *critical* particle density $\rho_c^{free}(\beta)$ *bounded* for a given temperature β^{-1} :

$$\begin{aligned} \rho_{c, n.n.}^{free}(\beta) &:= \lim_{\mu \uparrow 0} \lim_{\Lambda} \frac{1}{V} \sum_{q \in \Lambda^*} \frac{1}{e^{\beta(\epsilon(q)-\mu)} - 1} = \frac{1}{(2\pi)^d} \int_{\mathcal{B}^d} d^d q \frac{1}{e^{\beta\epsilon(q)} - 1} \\ &= \int_{\mathbb{R}_+} \mathcal{N}_d(d\epsilon) \frac{1}{e^{\beta\epsilon} - 1} < \infty . \end{aligned} \quad (2.9)$$

Here \lim_{Λ} stands for the thermodynamic limit $\Lambda \uparrow \mathbb{Z}^d$, by $\mathcal{B}^d := [-\pi, \pi]^d$ we denote the first *Brillouin zone* and the density of states $\mathcal{N}_d(d\epsilon) = \{c_d \epsilon^{(d/2-1)} + o(\epsilon^{(d/2-1)})\} d\epsilon$ for small ϵ .

A similar result is true for the *infinite-range* (i.r.) hopping Laplacian:

$$t_{xy}^\Lambda = \frac{1}{V} (1 - \delta_{x,y}) , \quad x, y \in \Lambda . \quad (2.10)$$

By (2.10) the one-particle spectrum in this case takes the form:

$$\epsilon(q) := (\hat{t}_0 - \hat{t}_q) = (1 - \delta_{q,0}) \geq 0 , \quad q \in \Lambda^* . \quad (2.11)$$

Therefore, it has a *gap*:

$$\lim_{q \rightarrow 0} \epsilon(q) = 1 \neq \epsilon(0) = 0, \quad (2.12)$$

and allowed values of the chemical potential are still $\mu \leq 0$. Since the density of states is simply zero in the gap, and $|\Lambda^*| = V|\mathcal{B}^d|$, we have $\mathcal{N}_d(d\epsilon) = \delta(\epsilon - 1)d\epsilon$. Therefore, the *critical* particle density has a bounded value:

$$\rho_{c, i.r.}^{free}(\beta) = \frac{1}{(2\pi)^d} \int_{\mathcal{B}^d} d^d q \frac{1}{e^\beta - 1} = \frac{1}{e^\beta - 1} < \infty, \quad (2.13)$$

for any dimensions. The latter implies a zero-mode BEC for densities $\rho > \rho_{c, i.r.}^{free}(\beta)$.

The problem of existence of BEC gets much less obvious if one takes into account the *boson interaction*. This is even the case for the simplest *on-site* repulsive interaction

$$H_\Lambda := T_\Lambda + \lambda \sum_{x \in \Lambda} n_x(n_x - 1), \quad \lambda \geq 0, \quad (2.14)$$

known as the *Bose-Hubbard* model. (Notice that *attraction*: $\lambda < 0$ makes this model unstable, see [U] for discussion of other cases.)

Remark 2.1 *Concerning the model (2.14) the best rigorous results so far are:*

- a proof of BEC for the *n.n.* lattice Laplacian and the hard-core boson repulsion: $\lambda = +\infty$, by [K-S] for the case of the half-filled lattice, see also [AB];
- a recent exact solution of the IRH Bose-Hubbard model (2.10), (2.14) for any $\lambda \geq 0$ by [BD].

The aim of the the present paper is to study a *disordered* IRH Bose-Hubbard model. Let $(\Omega, \Sigma, \mathbb{P})$ be a probability space. We define our basic model by the random Hamiltonian:

$$H_\Lambda^\omega = \frac{1}{2V} \sum_{x, y \in \Lambda} (a_x^* - a_y^*)(a_x - a_y) + \sum_{x \in \Lambda} \lambda_x^\omega n_x(n_x - 1) + \sum_{x \in \Lambda} \varepsilon_x^\omega n_x, \quad (2.15)$$

where parameters $\{\lambda_x^\omega \geq 0\}_{x \in \mathbb{Z}^d}$ and $\{\varepsilon_x^\omega \in \mathbb{R}^1\}_{x \in \mathbb{Z}^d}$, for $\omega \in \Omega$, are real-valued random fields on \mathbb{Z}^d , which we suppose to be *stationary* and *ergodic*. We denote by

$$p_\Lambda^\omega(\beta, \mu) := p[H_\Lambda^\omega](\beta, \mu) := \frac{1}{\beta V} \text{Tr}_{\mathfrak{F}_B} \exp \{-\beta(H_\Lambda^\omega - \mu N_\Lambda)\} \quad (2.16)$$

the grand canonical pressure of the system (2.15) for given temperature β^{-1} and chemical potential μ . For *non-random* parameters $\lambda_x^\omega = \lambda \geq 0$ and $\varepsilon_x^\omega = \varepsilon = 0$ the model (2.15) was considered in [BD].

Our main theorem is a formula for the pressure of this model given some general regularity conditions on the random parameters involved in the Hamiltonian (2.15).

Theorem 2.1 *Let the stationary, ergodic random fields $\{\lambda_x^\omega\}_{x \in \mathbb{Z}^d}$ and $\{\varepsilon_x^\omega\}_{x \in \mathbb{Z}^d}$ be such that:*

$$\lambda_{\min} := \inf_{x, \omega} \lambda_x^\omega > 0, \quad \varepsilon_{\min} := \inf_{x, \omega} \varepsilon_x^\omega > -\infty. \quad (2.17)$$

Then for almost all $\omega \in \Omega$, i.e., almost sure (a.s.), there exists a non-random thermodynamic limit of the pressure (2.16):

$$a.s. - \lim_{\Lambda} p_\Lambda^\omega(\beta, \mu) = p(\beta, \mu), \quad (2.18)$$

such that

$$p(\beta, \mu) = \sup_{r \geq 0} \left\{ -r^2 + \beta^{-1} \mathbb{E} \left\{ \ln \text{Tr}_{(\mathfrak{F}_B)_x} \exp \beta [(\mu - \varepsilon_x^\omega - 1)n_x - \lambda_x^\omega n_x(n_x - 1) + r(a_x^* + a_x)] \right\} \right\}, \quad (2.19)$$

where $\mathbb{E}(\cdot)$ is expectation with respect to the measure \mathbb{P} .

Proof: Let

$$H_{0\Lambda}^\omega := \sum_{x \in \Lambda} \lambda_x^\omega n_x(n_x - 1) + \sum_{x \in \Lambda} (\varepsilon_x^\omega + 1)n_x. \quad (2.20)$$

Then by definitions (2.4) the Hamiltonian (2.15) takes the form

$$H_\Lambda^\omega = T_\Lambda + \sum_{x \in \Lambda} \lambda_x^\omega n_x(n_x - 1) + \sum_{x \in \Lambda} \varepsilon_x^\omega n_x = -\hat{a}_0^* \hat{a}_0 + H_{0\Lambda}^\omega. \quad (2.21)$$

Since conditions (2.17) imply the estimate from below:

$$\begin{aligned} H_\Lambda^\omega &\geq -\hat{a}_0^* \hat{a}_0 + N_\Lambda + \lambda_{\min} \sum_{x \in \Lambda} n_x(n_x - 1) + \varepsilon_{\min} N_\Lambda \\ &\geq \frac{\lambda_{\min}}{V} N_\Lambda^2 + (\varepsilon_{\min} - \lambda_{\min}) N_\Lambda, \end{aligned} \quad (2.22)$$

the Hamiltonian (2.21) is *superstable*. Thus, the pressure in (2.18) is defined for all $\mu \in \mathbb{R}^1$.

Following [B-T], we introduce a similar Hamiltonian with *sources*:

$$H_\Lambda^\omega(\nu) := H_\Lambda^\omega - \sqrt{V}(\bar{\nu} \hat{a}_0 + \nu \hat{a}_0^*), \quad \nu \in \mathbb{C}, \quad (2.23)$$

and the corresponding *approximating* Hamiltonian:

$$H_{0\Lambda}^\omega(z, \nu) := H_{0\Lambda}^\omega(z) - \sqrt{V}(\bar{\nu} \hat{a}_0 + \nu \hat{a}_0^*), \quad (2.24)$$

where

$$H_{0\Lambda}^\omega(z) := H_{0\Lambda}^\omega + V|z|^2 - \sqrt{V}(\bar{z} \hat{a}_0 + z \hat{a}_0^*), \quad z \in \mathbb{C}. \quad (2.25)$$

Then

$$H_\Lambda^\omega(\nu) - H_\Lambda^\omega(z, \nu) = -(\hat{a}_0 - z\sqrt{V})^*(\hat{a}_0 - z\sqrt{V}), \quad (2.26)$$

and by virtue of the Bogoliubov *convexity inequality* one gets the estimates:

$$0 \leq p[H_\Lambda^\omega(\nu)] - p[H_\Lambda^\omega(z, \nu)] \leq \frac{1}{V} \left\langle (\hat{a}_0 - z\sqrt{V})^*(\hat{a}_0 - z\sqrt{V}) \right\rangle_{H_\Lambda^\omega(\nu)} \quad (2.27)$$

for each realization $\omega \in \Omega$. Here $\langle - \rangle_{H_\Lambda^\omega(\nu)} := \langle - \rangle_{H_\Lambda^\omega(\nu)}(\beta, \mu)$ denotes the grand-canonical quantum Gibbs state with Hamiltonian (2.23), and from now on we systematically omit the arguments (β, μ) . If we choose in the right-hand side of (2.27)

$$z = \frac{1}{\sqrt{V}} \langle \hat{a}_0 \rangle_{H_\Lambda^\omega(\nu)}, \quad (2.28)$$

then (2.27) implies the following estimate for each $\omega \in \Omega$:

$$0 \leq p[H_\Lambda^\omega(\nu)] - \sup_{z \in \mathbb{C}} p[H_\Lambda^\omega(z, \nu)] \leq \frac{1}{V} \langle \delta \hat{a}_0^* \delta \hat{a}_0 \rangle_{H_\Lambda^\omega(\nu)}, \quad (2.29)$$

where we denote

$$\delta\hat{a}_0 := \hat{a}_0 - \langle \hat{a}_0 \rangle_{H_\Lambda^\omega(\nu)}. \quad (2.30)$$

Since (2.5) implies the estimates:

$$-\sqrt{V}(\bar{\nu}\hat{a}_0 + \nu\hat{a}_0^*) \geq -|\nu|^2 \hat{a}_0^* \hat{a}_0 - V \geq -|\nu|^2 N_\Lambda - V, \quad (2.31)$$

by virtue of (2.22) and (2.31) the Hamiltonian with sources (2.23) is also *superstable*:

$$H_\Lambda^\omega(\nu) \geq \frac{\lambda_{\min}}{V} N_\Lambda^2 + (\varepsilon_{\min} - \lambda_{\min} - |\nu|^2) N_\Lambda - V, \quad (2.32)$$

uniformly in $\omega \in \Omega$ and in $|\nu| \leq C_0$, for a fixed $C_0 \geq 0$. The superstability (2.32) implies that there is a *monotonous nondecreasing* function $M := M(\beta, \mu) \geq 0$ of $\mu \in \mathbb{R}^1$, such that for any $\omega \in \Omega$ we have the bounds:

$$\begin{aligned} \left| \left\langle \hat{a}_0 / \sqrt{V} \right\rangle_{H_\Lambda^\omega(\nu)}(\beta, \mu) \right|^2 &= |\partial_{\bar{\nu}} p [H_\Lambda^\omega(\nu)](\beta, \mu)|^2 \\ &\leq \langle N_\Lambda / V \rangle_{H_\Lambda^\omega(\nu)}(\beta, \mu) = \partial_\mu p [H_\Lambda^\omega(\nu)](\beta, \mu) \leq M^2, \end{aligned} \quad (2.33)$$

and

$$|z_{\Lambda, \omega}(\beta, \mu; \nu)|^2 \leq M^2 \quad (2.34)$$

for the *maximizer* $z_{\Lambda, \omega}(\nu) := z_{\Lambda, \omega}(\beta, \mu; \nu)$ in (2.29):

$$p [H_\Lambda^\omega(z_{\Lambda, \omega}(\beta, \mu; \nu), \nu)](\beta, \mu) := \sup_{z \in \mathbb{C}} p [H_\Lambda^\omega(z, \nu)](\beta, \mu), \quad (2.35)$$

uniform in $|\nu| \leq C_0$. Notice that the maximizer satisfies the equation:

$$z_{\Lambda, \omega}(\nu) = \partial_{\bar{\nu}} p [H_\Lambda^\omega(z_{\Lambda, \omega}(\nu), \nu)] = \left\langle \hat{a}_0 / \sqrt{V} \right\rangle_{H_\Lambda^\omega(z_{\Lambda, \omega}(\nu), \nu)}. \quad (2.36)$$

Moreover, by the same line of reasoning as in [ZB], Ch.4 (see also [BD]) one gets that for $|\nu| < C_0$ there are some $u = u(M) > 0$ and $w = w(M) > 0$ such that

$$\langle \delta\hat{a}_0^* \delta\hat{a}_0 \rangle_{H_\Lambda^\omega(\nu)} \leq \{u + w(\delta\hat{a}_0^*, \delta\hat{a}_0)_{H_\Lambda^\omega(\nu)}\}, \quad (2.37)$$

where

$$(\delta\hat{a}_0^*, \delta\hat{a}_0)_{H_\Lambda^\omega(\nu)} = \beta^{-1} \partial_\nu \partial_{\bar{\nu}} p [H_\Lambda^\omega(\nu)]. \quad (2.38)$$

Then the estimates (2.29) and (2.37) imply:

$$0 \leq p [H_\Lambda^\omega(\nu)] - p [H_\Lambda^\omega(z_{\Lambda, \omega}(\nu), \nu)] \leq \frac{1}{V} \{u + w(\delta\hat{a}_0^*, \delta\hat{a}_0)_{H_\Lambda^\omega(\nu)}\}. \quad (2.39)$$

Following [PS] we define in the Hilbert space $L^2(\{(Re\nu, Im\nu) \in \mathbb{R}^2 : |\nu| < C_0\})$ the *Dirichlet* self-adjoint extension \hat{L}_V of the operator

$$L_V := I - w(\beta V)^{-1} \partial_\nu \partial_{\bar{\nu}}. \quad (2.40)$$

Here $4\partial_\nu \partial_{\bar{\nu}} = \Delta$ coincides with the two-dimensional Laplacian operator in variables $(Re\nu, Im\nu)$. The operator \hat{L}_V is invertible and \hat{L}_V^{-1} has the kernel $(\hat{L}_V^{-1})(\nu, \nu')$ (*Green function*), and

$(\hat{L}_V^{-1})(\nu, \nu') = 0$ for $|\nu| = C_0$, or $|\nu'| = C_0$, by the Dirichlet boundary condition. Since the semigroup $\left\{ \exp[-t(\hat{L}_V - I)] \right\}_{t \geq 0}$ is *positivity preserving*, the same property is true for the operator \hat{L}_V^{-1} , see e.g. [RS2], Ch.X.4.

Now, let $p(\nu) := p[H_\Lambda^\omega(\nu)]$ and $p_0(\nu) := p[H_\Lambda^\omega(z_{\Lambda, \omega}(\nu), \nu)]$. Since \hat{L}_V^{-1} is positivity preserving, then (2.39)-(2.40) imply

$$\left(\hat{L}_V^{-1}(p_0 + u/V) \right) (\nu) \geq p(\nu), \quad (2.41)$$

and by consequence the estimates

$$\begin{aligned} 0 &\leq p[H_\Lambda^\omega(\nu)] - p[H_\Lambda^\omega(z_{\Lambda, \omega}(\nu), \nu)] \leq \left(\hat{L}_V^{-1}(p_0 + u/V) \right) (\nu) - p_0(\nu) \\ &\leq \int_{|\nu'| < C_0} d\nu' \left(\hat{L}_V^{-1} \right) (\nu, \nu') \{p_0(\nu') - p_0(\nu)\} + u/V, \end{aligned} \quad (2.42)$$

where we used that $\int_{|\nu'| < C_0} d\nu' \left(\hat{L}_V^{-1} \right) (\nu, \nu') = 1$, $|\nu| < C_0$. By virtue of (2.34) and (2.36) we obtain for the integral in the right-hand side of (4.40) the estimate:

$$\int_{|\nu'| < C_0} d\nu' \left(\hat{L}_V^{-1} \right) (\nu, \nu') \{p_0(\nu') - p_0(\nu)\} \leq 2M \int_{|\nu'| < C_0} d\nu' \left(\hat{L}_V^{-1} \right) (\nu, \nu') |\nu' - \nu| = I_V. \quad (2.43)$$

After change of variables to $\xi = \nu\sqrt{V}$, we get

$$I_V = \frac{2M}{V} \int_{|\xi'| < C_0\sqrt{V}} d\xi' \left(\hat{L}_{V=1}^{-1} \right) (\xi, \xi') |\xi' - \xi| \leq \frac{\tilde{M}}{V}. \quad (2.44)$$

Here we used that in \mathbb{R}^2 the *Green* function is known explicitly:

$$\left(\hat{L}_\infty^{-1} \right) (\xi, \xi') = \frac{w}{2\pi\beta} K_0\left(\frac{\beta}{w} |\xi - \xi'|\right), \quad (2.45)$$

where the Bessel function $K_0(x) \simeq \sqrt{\pi/2x} \exp(-x)$ decays exponentially fast for large $x > 0$. Therefore, (2.42) and (2.44) imply

$$0 \leq p[H_\Lambda^\omega(\nu)] - p[H_\Lambda^\omega(z_{\Lambda, \omega}(\nu), \nu)] \leq O(1/V), \quad (2.46)$$

for all $\omega \in \Omega$, any $\beta > 0$, $\mu \in \mathbb{R}^1$ and $|\nu| < C_0$.

Notice that by definitions (2.20) and (2.25) for any $z, \nu \in \mathbb{C}$ we get:

$$\begin{aligned} p_{\Lambda, \text{appr}}^\omega(\beta, \mu; z, \nu) &:= p[H_\Lambda^\omega(z, \nu)](\beta, \mu) = -|z|^2 + \\ &+ \frac{1}{\beta V} \sum_{x \in \Lambda} \ln \text{Tr}_{\mathfrak{F}_x} \exp \beta [(\mu - \varepsilon_x^\omega - 1)n_x - \lambda_x^\omega n_x(n_x - 1) + (z + \nu)a_x^* + (\bar{z} + \bar{\nu})a_x]. \end{aligned} \quad (2.47)$$

Then ergodicity of the random fields $\{\lambda_x^\omega\}_{x \in \mathbb{Z}^d}$ and $\{\varepsilon_x^\omega\}_{x \in \mathbb{Z}^d}$ implies the existence of the *a.s.* limit:

$$\begin{aligned} p_{\text{appr}}(\beta, \mu; z, \nu) &= a.s. - \lim_{\Lambda} p_{\Lambda, \text{appr}}^\omega(\beta, \mu; z, \nu) = -|z|^2 + \\ &+ \beta^{-1} \mathbb{E} \left\{ \ln \text{Tr}_{\mathfrak{F}_x} \exp \beta [(\mu - \varepsilon_x^\omega - 1)n_x - \lambda_x^\omega n_x(n_x - 1) + (z + \nu)a_x^* + (\bar{z} + \bar{\nu})a_x] \right\}, \end{aligned} \quad (2.48)$$

i.e., the *self-averaging* [PF] of the limiting approximating pressure $p_{\text{appr}}^\omega(\beta, \mu; z, \nu)$.

Now we put the source $\nu \rightarrow 0$ and we make the canonical (*gauge*) transformation:

$$\tilde{a}_x := a_x e^{i \arg z}. \quad (2.49)$$

Since Hamiltonian (2.25) is invariant with respect of this transformation, we get that $z = |z| := r$ and (cf.(2.47)):

$$\begin{aligned} \tilde{p}_{\Lambda, \text{appr}}^\omega(\beta, \mu; r) &:= p_{\Lambda, \text{appr}}^\omega(\beta, \mu; z = r, \nu = 0) = p[H_\Lambda^\omega(r, 0)](\beta, \mu) = -r^2 + \\ &+ \frac{1}{\beta V} \sum_{x \in \Lambda} \ln \text{Tr}_{\mathfrak{F}_x} \exp \beta [(\mu - \varepsilon_x^\omega - 1)n_x - \lambda_x^\omega n_x(n_x - 1) + r(\tilde{a}_x^* + \tilde{a}_x)]. \end{aligned} \quad (2.50)$$

Therefore, without source the *maximizers* in (2.35) can be defined only up to a phase and their moduli satisfy the equation:

$$r = \frac{1}{2V} \sum_{x \in \Lambda} \langle \tilde{a}_x + \tilde{a}_x^* \rangle_{H_\Lambda^\omega(r, 0)} =: \xi_\Lambda^\omega(r), \quad (2.51)$$

where

$$\begin{aligned} \xi_x^\omega(r) &:= \langle \tilde{a}_x + \tilde{a}_x^* \rangle_{H_\Lambda^\omega(r, 0)} = \\ &= \frac{\text{Tr}_{\mathfrak{F}_x} \{(\tilde{a}_x + \tilde{a}_x^*) \exp \beta [(\mu - \varepsilon_x^\omega - 1)n_x - \lambda_x^\omega n_x(n_x - 1) + r(\tilde{a}_x^* + \tilde{a}_x)]\}}{\text{Tr}_{\mathfrak{F}_x} \exp \beta [(\mu - \varepsilon_x^\omega - 1)n_x - \lambda_x^\omega n_x(n_x - 1) + r(\tilde{a}_x^* + \tilde{a}_x)]}. \end{aligned} \quad (2.52)$$

When $r = 0$, the approximating Hamiltonian (2.25) is invariant with respect to canonical gauge transformations $\mathcal{U}_\varphi \tilde{a}_x \mathcal{U}_\varphi^* = \tilde{a}_x e^{i\varphi}$ for any φ . This implies $\xi_x^\omega(r = 0) = 0$. Hence, equation (2.51) always has a trivial solution $r = 0$ and, moreover, by (2.34) any nontrivial solution $r_\Lambda^\omega \leq M$.

Finally, differentiating (2.52) with respect to r we obtain:

$$0 \leq \partial_r \xi_x^\omega(r) \leq R, \quad (2.53)$$

where, by the superstability (2.32), the upper bound R is finite uniformly in ω, r, x . Hence, $-2M \leq \partial_r \tilde{p}_{\Lambda, \text{appr}}^\omega(\beta, \mu; r) \leq 2RM$ for $r \in [0, M]$. By consequence the limit (2.48) implies the *uniform a.s.* convergence of the sequence $\{\tilde{p}_{\Lambda, \text{appr}}^\omega(\beta, \mu; r)\}_\Lambda$ for $r \in [0, M]$:

$$\begin{aligned} \tilde{p}_{\text{appr}}(\beta, \mu; r) &= a.s. - \lim_{\Lambda} \tilde{p}_{\Lambda, \text{appr}}^\omega(\beta, \mu; r) = \\ &= -r^2 + \beta^{-1} \mathbb{E} \{ \ln \text{Tr}_{\mathfrak{F}_x} \exp \beta [(\mu - \varepsilon_x^\omega - 1)n_x - \lambda_x^\omega n_x(n_x - 1) + r(\tilde{a}_x^* + \tilde{a}_x)] \}, \end{aligned} \quad (2.54)$$

Therefore,

$$a.s. - \lim_{\Lambda} \sup_{r \geq 0} \tilde{p}_{\Lambda, \text{appr}}^\omega(\beta, \mu; r) = \sup_{r \geq 0} \tilde{p}_{\text{appr}}(\beta, \mu; r). \quad (2.55)$$

Together with (2.46) and (2.48), the limit (2.55) proves the assertions (2.18) and (2.19) of the theorem. \square

Remark 2.2 *The function $\xi_x^\omega(r)$ is increasing in r by virtue of (2.53). Moreover, it has also been suggested that for any $x \in \mathbb{Z}^d$ and $\omega \in \Omega$, the function $r \mapsto \xi_x^\omega(r)$ is concave, see [BD] for discussion of this conjecture. This implies that the nontrivial solution of equation (2.51) is unique. Notice that homogeneity and ergodicity of the random field random field $\{\varepsilon_x^\omega\}_{x \in \mathbb{Z}^d}$*

implies the same for the random field $\{\xi_x^\omega\}_{x \in \mathbb{Z}^d}$ defined by (2.52). Therefore, equation (2.51) in the thermodynamic limit takes the form:

$$r = a.s. - \lim_{\Lambda} \xi_{\Lambda}^{\omega}(r) = \frac{1}{2} \mathbb{E}(\xi_{x=0}^{\omega}(r)) =: f(r), \quad (2.56)$$

expressing a self-averaging property of the order parameter r , see [PF]. Since the expectation in (2.56) preserves convexity, solution of the limit equation (2.56) should be also unique. Therefore, the sequence of maximizers $\{r_{\Lambda}^{\omega}\}_{\Lambda}$ with $\mathbb{P} = 1$ has a unique accumulation point in the interval $[0, M]$. Moreover, if r_{Λ}^{ω} is the unique solution of equation (2.51), then

$$a.s. - \lim_{\Lambda} r_{\Lambda}^{\omega} = r(\beta, \mu), \quad (2.57)$$

where $r(\beta, \mu)$ denotes the unique solution of equation (2.56).

Proof: Since $\lambda_{\min} > 0$, by superstability we get $r_{\Lambda}^{\omega} \leq M$, see (2.34), i.e.

$$0 \leq \liminf_{\Lambda} r_{\Lambda}^{\omega} \leq \limsup_{\Lambda} r_{\Lambda}^{\omega} \leq M, \quad (2.58)$$

for any $\omega \in \Omega$. Now suppose that there exists $\Omega_{>}$ with $\mathbb{P}(\Omega_{>}) > 0$ and a subsequence $\{r_{\Lambda_n}^{\omega}\}_{n \geq 1}$, $\omega \in \Omega_{>}$ such that

$$\lim_{n \rightarrow \infty} r_{\Lambda_n}^{\omega} = r_*^{\omega} > r(\beta, \mu), \quad \omega \in \Omega_{>}. \quad (2.59)$$

Then, by virtue of (2.51), (2.53), (2.56) and (2.59) we get:

$$\xi_{\Lambda_n}^{\omega}(r_*^{\omega}) - R |r_{\Lambda_n}^{\omega} - r_*^{\omega}| \leq r_{\Lambda_n}^{\omega} = \xi_{\Lambda_n}^{\omega}(r_*^{\omega} + r_{\Lambda_n}^{\omega} - r_*^{\omega}) \leq \xi_{\Lambda_n}^{\omega}(r_*^{\omega}) + R |r_{\Lambda_n}^{\omega} - r_*^{\omega}|. \quad (2.60)$$

These estimates, together with the limit (2.59) and a.s.-convergence of $\xi_{\Lambda_n}^{\omega}(r)$ to $f(r)$ for any r imply

$$r_*^{\omega} = f(r_*^{\omega}) > r(\beta, \mu), \quad (2.61)$$

for any $\omega \in \Omega_{>}$ with $\mathbb{P}(\Omega_{>}) > 0$, which is impossible by uniqueness of solution of (2.56). Similarly one excludes the hypothesis $r_*^{\omega} < r(\beta, \mu)$, which proves (2.57). \square

3 Limiting Hamiltonians

3.1 Limit of Hard-Core Bosons

The *hard-core* (h.c.) interaction in the Bose-Hubbard model (2.14) corresponds to $\lambda = +\infty$, or $\lambda_{\min} = +\infty$ for the IRH Bose-Hubbard model (2.15). This formally discards from the boson Fock space $\mathfrak{F}_B(\Lambda)$ all vectors with *more than one* particle at one site.

Let Φ_0 denote the *vacuum vector* in $\mathfrak{F}_B(\Lambda)$. Then the subspace $\mathfrak{F}_B^{h.c.}(\Lambda) \subset \mathfrak{F}_B(\Lambda)$, which corresponds to the hard-core restrictions, is spanned by the orthonormal vectors

$$\Phi_X = \prod_{x \in X} a_x^* \Phi_0, \quad X \subset \Lambda. \quad (3.1)$$

Since the subspace $\mathfrak{F}_B^{h.c.}(\Lambda)$ is closed, there is orthogonal projection P_{Λ} onto $\mathfrak{F}_B^{h.c.}(\Lambda)$ such that

$$\mathfrak{F}_B^{h.c.}(\Lambda) = P \mathfrak{F}_B(\Lambda), \quad (3.2)$$

and we get the representation

$$\mathfrak{F}_B(\Lambda) = \mathfrak{F}_B^{h.c.}(\Lambda) \oplus (\mathfrak{F}_B^{h.c.}(\Lambda))^\perp, \quad (3.3)$$

where the orthogonal compliment $(\mathfrak{F}_B^{h.c.}(\Lambda))^\perp := (I - P)\mathfrak{F}_B(\Lambda)$.

Since our main Theorem 2.1 is valid for any $\lambda_{\min} > 0$ and the estimate (2.46) is uniform in λ_x^ω , we can extend this theorem to the hard-core case by taking the limit $\lambda_{\min} \rightarrow +\infty$.

For simplicity we consider the case of a sequence of non-random identical and increasing positive $\{\lambda_x^\omega = \lambda_s > 0\}_{s=1}^\infty$ such that $\lambda_s \rightarrow +\infty$.

Lemma 3.1 *Let $\lambda_s \rightarrow +\infty$. Then for all $\zeta \in \mathbb{C} : \text{Im}(\zeta) \neq 0$, and for any $\omega \in \Omega$ and $\nu \in \mathbb{C}$ we have the strong resolvent convergence of Hamiltonians (2.23):*

$$\lim_{\lambda_s \rightarrow +\infty} (H_\Lambda^\omega(s, \nu) - \zeta I)^{-1} \Psi = P \left[T_\Lambda + \sum_{x \in \Lambda} \varepsilon_x^\omega n_x - \sqrt{V}(\bar{\nu} \hat{a}_0 + \nu \hat{a}_0^*) - \zeta I \right]^{-1} P \Psi, \quad \Psi \in \mathfrak{F}_B(\Lambda), \quad (3.4)$$

where

$$H_\Lambda^\omega(s, \nu) := T_\Lambda + \lambda_s \sum_{x \in \Lambda} n_x(n_x - 1) + \sum_{x \in \Lambda} \varepsilon_x^\omega n_x - \sqrt{V}(\bar{\nu} \hat{a}_0 + \nu \hat{a}_0^*). \quad (3.5)$$

The same is true for approximating Hamiltonians (2.24):

$$\lim_{\lambda_s \rightarrow +\infty} (H_\Lambda^{\omega, \text{appr}}(s, z, \nu) - \zeta I)^{-1} \Psi = P \left[V |z|^2 - \sqrt{V}(\bar{z} \hat{a}_0 + z \hat{a}_0^*) + \sum_{x \in \Lambda} (\varepsilon_x^\omega + 1) n_x - \sqrt{V}(\bar{\nu} \hat{a}_0 + \nu \hat{a}_0^*) - \zeta I \right]^{-1} P \Psi, \quad (3.6)$$

for any $z \in \mathbb{C}$ and $\Psi \in \mathfrak{F}_B(\Lambda)$. Here

$$H_\Lambda^{\omega, \text{appr}}(s, z, \nu) := V |z|^2 - \sqrt{V}(\bar{z} \hat{a}_0 + z \hat{a}_0^*) + N_\Lambda + \lambda_s \sum_{x \in \Lambda} n_x(n_x - 1) + \sum_{x \in \Lambda} \varepsilon_x^\omega n_x - \sqrt{V}(\bar{\nu} \hat{a}_0 + \nu \hat{a}_0^*). \quad (3.7)$$

Proof: By estimate (2.32) and (3.5) for $0 < \lambda_s < \lambda_{s+1}$ we get:

$$\frac{\lambda_s}{V} N_\Lambda^2 + (\varepsilon_{\min} - \lambda_s - |\nu|^2) N_\Lambda - V \leq H_\Lambda^\omega(s, \nu) \leq H_\Lambda^\omega(s+1, \nu). \quad (3.8)$$

So, for any $\omega \in \Omega$ and $\nu \in \mathbb{C}$ Hamiltonians (3.5) form an increasing sequence of self-adjoint operators, semi-bounded from below. Let $\{h_s^\omega(\nu, \Lambda)[\Psi] := (\Psi, H_\Lambda^\omega(s, \nu)\Psi)_{\mathfrak{F}_B(\Lambda)}\}_{s=1}^\infty$ be the corresponding monotonic sequence of closed symmetric quadratic forms with domains $\text{dom } h_s^\omega(\nu, \Lambda)$. Put

$$Q := \bigcap_{s \geq 1} \text{dom } h_s^\omega(\nu, \Lambda), \quad (3.9)$$

and let $Q_0 = \overline{Q}$ be the closure of Q in the Hilbert space $\mathfrak{F}_B(\Lambda)$. Since for any $\omega \in \Omega$ and $\nu \in \mathbb{C}$

$$\lim_{\lambda_s \rightarrow +\infty} (\Psi, H_\Lambda^\omega(s, \nu)\Psi)_{\mathfrak{F}_B(\Lambda)} = +\infty, \quad \Psi \in (\mathfrak{F}_B^{h.c.}(\Lambda))^\perp, \quad (3.10)$$

one gets $Q_0 = \mathfrak{F}_B^{h.c.}(\Lambda)$ and the strong resolvent convergence (3.4) of Hamiltonians, see e.g. [D], Ch.4.4 or [NZ], Lemma 2.10. (Note that for hard cores the space $\mathfrak{F}_B^{h.c.}(\Lambda)$ is finite-dimensional,

which makes these arguments even simpler.) The strong resolvent convergence (3.4) of Hamiltonians implies also

$$\begin{aligned} \lim_{\lambda_s \rightarrow +\infty} (\Phi, H_\Lambda^\omega(s, \nu) \Phi)_{\mathfrak{F}_B(\Lambda)} = & \quad (3.11) \\ (\Phi, P[T_\Lambda + \sum_{x \in \Lambda} \varepsilon_x^\omega n_x - \sqrt{V}(\bar{\nu} \hat{a}_0 + \nu \hat{a}_0^*)] P \Phi)_{\mathfrak{F}_B^{h.c.}(\Lambda)}, \quad \Phi \in \mathfrak{F}_B^{h.c.}(\Lambda). \end{aligned}$$

The same line of reasoning leads to (3.6) for approximating Hamiltonians. \square

By the Trotter approximating theorem [RS1] the convergence (3.4) and (3.6) yields the strong convergence of the Gibbs semigroups:

Corollary 3.1 *The following strong limits exist:*

$$s - \lim_{\lambda_s \rightarrow +\infty} e^{-\beta H_\Lambda^\omega(s, \nu)} = e^{-\beta H_{h.c., \Lambda}^\omega(\nu)}, \quad (3.12)$$

where

$$H_{h.c., \Lambda}^\omega(\nu) := P[T_\Lambda + \sum_{x \in \Lambda} \varepsilon_x^\omega n_x - \sqrt{V}(\bar{\nu} \hat{a}_0 + \nu \hat{a}_0^*)] P, \quad (3.13)$$

and similarly

$$s - \lim_{\lambda_s \rightarrow +\infty} e^{-\beta H_\Lambda^{\omega, \text{appr}}(s, z, \nu)} = e^{-\beta H_{h.c., \Lambda}^{\omega, \text{appr}}(z, \nu)}, \quad \text{dom } H_{h.c., \Lambda}^\omega(\nu) = \mathfrak{F}_B^{h.c.}(\Lambda), \quad (3.14)$$

where

$$H_{h.c., \Lambda}^{\omega, \text{appr}}(z, \nu) := P[V|z|^2 - \sqrt{V}(\bar{z} \hat{a}_0 + z \hat{a}_0^*) + \sum_{x \in \Lambda} (\varepsilon_x^\omega + 1) n_x - \sqrt{V}(\bar{\nu} \hat{a}_0 + \nu \hat{a}_0^*)] P, \quad (3.15)$$

with $\text{dom } H_{h.c., \Lambda}^{\omega, \text{appr}}(z, \nu) = \mathfrak{F}_B^{h.c.}(\Lambda)$.

Since $\{e^{-\beta(H_\Lambda^\omega(s, \nu) - \mu N_\Lambda)}\}_{s \geq 1}$ is a sequence of trace-class operators from $\mathcal{C}_1(\mathfrak{F}_B(\Lambda))$ monotonously decreasing to the trace-class operator

$$e^{-\beta(H_{h.c., \Lambda}^\omega(\nu) - \mu N_\Lambda)} \in \mathcal{C}_1(\mathfrak{F}_B^{h.c.}(\Lambda)),$$

the convergence (3.12) can be lifted to the trace-norm topology, see [Z]. The same is true for (3.14). It then follows that the pressures also converge:

Lemma 3.2

$$\lim_{\lambda_s \rightarrow +\infty} p[H_\Lambda^\omega(s, \nu)] = p[H_{h.c., \Lambda}^\omega(\nu)], \quad (3.16)$$

$$\lim_{\lambda_s \rightarrow +\infty} p[H_\Lambda^\omega(s, z, \nu)] = p[H_{h.c., \Lambda}^{\omega, \text{appr}}(z, \nu)]. \quad (3.17)$$

Since the estimate (2.46) is uniform in $\lambda \geq \lambda_{\min} > 0$, we can take the limit $\lambda_s \rightarrow +\infty$ to obtain

$$0 \leq p[H_{h.c., \Lambda}^\omega(\nu)] - p[H_{h.c., \Lambda}^{\omega, \text{appr}}(z_{\Lambda, \omega}(\nu), \nu)] \leq O(1/V), \quad (3.18)$$

for all $\omega \in \Omega$, any $\beta > 0$, $\mu \in \mathbb{R}^1$ and $|\nu| < C_0$. Then, by the same line of reasoning as after (2.46) in Theorem 2.1, we obtain the thermodynamic limit of the pressure for the hard-core bosons:

Corollary 3.2 *The pressure of the Infinite-Range-Hopping hard-core Bose-Hubbard model with randomness is given by*

$$p_{h.c.}(\beta, \mu) = \sup_{r \geq 0} \left\{ -r^2 + \beta^{-1} \mathbb{E} \left\{ \ln \operatorname{Tr}_{(\mathfrak{F}_B^{h.c.})_x} \exp(\beta P [(\mu - \varepsilon_x^\omega - 1)n_x + r(a_x^* + a_x)] P) \right\} \right\}, \quad (3.19)$$

cf. expression (2.19) for finite λ .

Remark 3.1 *To calculate the Tr over $\mathfrak{F}_B^{h.c.}$ note that the boson creation and annihilation operators are quite different from operators: $c_x^* := Pa_x^*P$, $c_x := Pa_xP$ restricted to $\operatorname{dom} c_x^* = \operatorname{dom} c_x = \mathfrak{F}_B^{h.c.}$, which occur in (3.19). The major difference consists in their commutation relations:*

$$[c_x, c_y^*] = 0, \quad (x \neq y), \quad (c_x)^2 = (c_x^*)^2 = 0, \quad c_x c_x^* + c_x^* c_x = I. \quad (3.20)$$

Taking the XY representation of relations (3.20):

$$c_x = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad c_x^* = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix},$$

(3.19) gives explicitly

$$p_{h.c.}(\beta, \mu) = \sup_{r \geq 0} \left\{ -r^2 + \mathbb{E} \left\{ \frac{1}{2}(\mu - \varepsilon_x^\omega - 1) + \beta^{-1} \ln \left[2 \cosh \left(\frac{1}{2} \beta \sqrt{(\mu - \varepsilon_x^\omega - 1)^2 + 4r^2} \right) \right] \right\} \right\}, \quad (3.21)$$

the grand-canonical pressure for the random IRH hard-core Bose-Hubbard model.

3.2 Limit of Perfect Bosons

The limit $\lambda \rightarrow 0$ is more delicate. For simplicity, below we assume that $\varepsilon_{\min} = 0$. Then Hamiltonian (2.15) for perfect bosons $\lambda_x^\omega = 0$ is non-negative, i.e. the corresponding pressure exists in a finite volume only for *negative* chemical potentials. There is an analogue of Lemma 3.1, if we subtract from this Hamiltonian a term μN_Λ with $\mu < 0$ and assume ν small enough:

Lemma 3.3 *Assume that $\varepsilon_{\min} = 0$ and let $\lambda_s \searrow 0$. Then for $\mu < 0$, for all $\zeta \in \mathbb{C} : \operatorname{Im}(\zeta) \neq 0$, and for any $\omega \in \Omega$, we have the strong resolvent convergence of Hamiltonians (2.23):*

$$\lim_{\lambda_s \searrow 0} (H_\Lambda^\omega(s, \nu) - \mu N_\Lambda - \zeta I)^{-1} \Psi = \{T_\Lambda + \sum_{x \in \Lambda} (\varepsilon_x^\omega - \mu)n_x - \sqrt{V}(\bar{\nu}\hat{a}_0 + \nu\hat{a}_0^*) - \zeta I\}^{-1} \Psi, \quad \Psi \in \mathfrak{F}_B(\Lambda), \quad (3.22)$$

for $\nu \in \mathbb{C}$, if $|\nu|^2 < |\mu|$. The same is true for approximating Hamiltonians (2.24):

$$\lim_{\lambda_s \searrow 0} (H_\Lambda^{\omega, \text{appr}}(s, z, \nu) - \mu N_\Lambda - \zeta I)^{-1} \Psi = \{V|z|^2 - \sqrt{V}(\bar{z}\hat{a}_0 + z\hat{a}_0^*) + \sum_{x \in \Lambda} (\varepsilon_x^\omega + 1 - \mu)n_x - \sqrt{V}(\bar{\nu}\hat{a}_0 + \nu\hat{a}_0^*) - \zeta I\}^{-1} \Psi, \quad (3.23)$$

for any $z \in \mathbb{C}$, $\zeta \in \mathbb{C} : \operatorname{Im}(\zeta) \neq 0$ and $\Psi \in \mathfrak{F}_B(\Lambda)$.

Proof: The bound (2.32) now yields:

$$H_\Lambda^\omega(s, \nu, \mu) := H_\Lambda^\omega(s, \nu) - \mu N_\Lambda \geq (-\mu - |\nu|^2)N_\Lambda - V, \quad (3.24)$$

so that for $|\nu|^2 + \mu < 0$, the operators $\{H_\Lambda^\omega(s, \nu, \mu)\}_{s \geq 1}$ are positive. As in Lemma 3.1, for these operators we define the corresponding closed symmetric quadratic forms by $\{h_s^\omega(\nu, \mu, \Lambda)[\Psi] := (\Psi, H_\Lambda^\omega(s, \nu, \mu)\Psi)_{\tilde{\mathfrak{H}}_B(\Lambda)}\}_{s=1}^\infty$. Note that they are monotonously decreasing and bounded from below, which implies that for any $\omega \in \Omega$, $\nu \in \mathbb{C}$ and Λ the operators $\{H_\Lambda^\omega(s, \nu, \mu)\}_{s \geq 1}$ converge in the strong resolvent sense, see e.g. [K], Ch.VIII, to a positive self-adjoint operator $H_{\Lambda,0}^\omega(\nu, \mu)$. Let us define the symmetric form

$$h_\infty^\omega[\Phi] = \lim_{s \rightarrow \infty} h_s^\omega[\Phi], \quad (3.25)$$

with domain

$$\text{dom}(h_\infty^\omega) = \bigcup_{s \geq 1} \text{dom}(h_s^\omega).$$

It is known, [K] Ch.VIII, that if the form (3.25) is closable, then operator $H_{\Lambda,0}^\omega(\nu, \mu)$ is associated with the closure \tilde{h}_∞^ω . By explicit expression of $h_s^\omega(\nu, \mu, \Lambda)$ one gets that the limit form (3.25) is closable (and even closed), since it is associated with the self-adjoint operator $H_\Lambda^\omega(s = \infty, \nu, \mu)$. Then the operator $H_{\Lambda,0}^\omega(\nu, \mu)$ associated with the closure \tilde{h}_∞^ω of (3.25) simply coincides with $H_\Lambda^\omega(s = \infty, \nu, \mu)$:

$$\tilde{h}_\infty^\omega[\Phi] = (\Phi, [T_\Lambda + \sum_{x \in \Lambda} (\varepsilon_x^\omega - \mu)n_x - \sqrt{V}(\bar{\nu}\hat{a}_0 + \nu\hat{a}_0^*)] \Phi),$$

that proves (3.22).

A similar argument applies for the approximating Hamiltonians (2.24). But, in contrast to the case of sources $|\nu|^2 < |\mu|$, that we can choose as small as we want to apply the main Theorem 2.1, the value of z will be defined by variational principle (2.19) with $\lambda_x^\omega \geq 0$. Now the semi-boundedness of $\{H_\Lambda^{\omega,appr}(s, z, \nu)\}_{s \geq 1}$ from below follows from the estimate

$$\sum_{x \in \Lambda} (\varepsilon_x^\omega + 1 - \mu)n_x - \sqrt{V}((\bar{\nu} + \bar{z})\hat{a}_0 + (\nu + z)\hat{a}_0^*) \geq -V \frac{|\nu + z|^2}{1 - \mu}. \quad (3.26)$$

The rest of the arguments is identical to those for the operators (3.24), or equivalently for the sequence $\{H_\Lambda^\omega(s, \nu)\}_{s \geq 1}$, and goes through verbatim to give the proof of the limit (3.23) with $H_\Lambda^{\omega,appr}(s = \infty, z, \nu) := H_{\Lambda,0}^{\omega,appr}(z, \nu)$. \square

Corollary 3.3 *In a full analogy with Corollary 3.1 and Lemma 3.2, the Trotter approximation theorem and the monotonicity of the operator families $\{H_\Lambda^\omega(s, \nu)\}_{s \geq 1}$, $\{H_\Lambda^{\omega,appr}(s, z, \nu)\}_{s \geq 1}$ yield*

$$\lim_{\lambda_s \rightarrow 0} p[H_\Lambda^\omega(s, \nu)] = p[H_{\Lambda,0}^\omega(\nu)], \quad (3.27)$$

$$\lim_{\lambda_s \rightarrow 0} p[H_\Lambda^{\omega,appr}(s, z, \nu)] = p[H_{\Lambda,0}^{\omega,appr}(z, \nu)]. \quad (3.28)$$

Notice that, similarly to the Weakly Imperfect Bose-Gas [ZB], the estimate (2.46) for $\mu < 0$ is still uniform in $\lambda \geq 0$. Therefore, we can take there the limit $\lambda_s \rightarrow 0$ to obtain

$$0 \leq p[H_{\Lambda,0}^\omega(\nu)] - p[H_{\Lambda,0}^{\omega,appr}(z_{\Lambda,\omega}(\nu), \nu)] \leq O(1/V), \quad (3.29)$$

for all $\omega \in \Omega$, any $\beta > 0$ and $|\nu|^2 < -\mu$. Then, following the same line of reasoning as after (2.46) in Theorem 2.1, we obtain the thermodynamic limit of the pressure for the perfect bosons:

$$p_0(\beta, \mu < 0) = \sup_{r \geq 0} \left\{ -r^2 + \beta^{-1} \mathbb{E} \left\{ \ln \operatorname{Tr}_{(\mathfrak{F}_B)_x} \exp(\beta [(\mu - \varepsilon_x^\omega - 1)n_x + r(a_x^* + a_x)]) \right\} \right\} , \quad (3.30)$$

cf. expression (2.19) for finite λ , where all values of μ are allowed. Since we put $\varepsilon_{\min} = 0$, the variational principle in (3.30) implies:

$$p_0(\beta, \mu < 0) = \beta^{-1} \mathbb{E} \left\{ \ln \operatorname{Tr}_{(\mathfrak{F}_B)_x} \exp(\beta [(\mu - \varepsilon_x^\omega - 1)n_x]) \right\} = \beta^{-1} \mathbb{E} \left\{ \ln [1 - \exp\{\beta(\mu - \varepsilon_x^\omega - 1)\}]^{-1} \right\} . \quad (3.31)$$

The convexity of $\{p [H_{\Lambda,0}^\omega(\nu = 0)]\}_\Lambda$ and the thermodynamic limit $p_0(\beta, \mu)$ as the functions of $\mu < 0$, together with the Griffith lemma, see e.g. [ZB], yield the convergence of derivative with respect of μ , i.e. the formula for the total particle density:

$$\rho(\beta, \mu < 0) = \mathbb{E} \left[\frac{1}{e^{\beta(1+\varepsilon^\omega-\mu)} - 1} \right] . \quad (3.32)$$

Remark 3.2 As usually in the case of the perfect boson gas one recovers the value of thermodynamic parameters at extreme point $\mu = 0$ by continuation: $\mu \rightarrow -0$:

$$p_0(\beta, \mu = 0) := \beta^{-1} \mathbb{E} \left\{ \ln [1 - \exp\{\beta(-\varepsilon_x^\omega - 1)\}]^{-1} \right\} , \quad (3.33)$$

$$\rho(\beta, \mu = 0) := \mathbb{E} \left[\frac{1}{e^{\beta(1+\varepsilon^\omega)} - 1} \right] . \quad (3.34)$$

In particular by (3.34) it gets clear that the gap (= 1) in the one-particle spectrum of the perfect boson gas T_Λ and $\varepsilon_{\min} = 0$ imply that the critical density

$$\rho_c(\beta) := \sup_{\mu < 0} \rho(\beta, \mu) = \rho(\beta, \mu = 0) \quad (3.35)$$

is finite, cf. (2.12) and (2.13). This opens a room for the zero-mode Bose condensation in the case of the random potential $\{\varepsilon_x^\omega\}_x$.

4 Phase Diagram

Here we analyse only the case, when ε_x^ω is random, but the interaction couplings $\lambda_x^\omega = \lambda \geq 0$ are fixed.

To proceed we recall first the formulae determining the critical temperature $\beta_c(\rho, \lambda)^{-1}$ for the *nonrandom* case $\varepsilon_x^\omega = 0$. To this end we define, cf (2.50),

$$\tilde{p}(\beta, \mu, \lambda; r) := \frac{1}{\beta} \ln \operatorname{Tr}_{\mathcal{H}} \exp(-\beta [h_n(\mu, \lambda) - r(a^* + a)]) , \quad (4.1)$$

where

$$h_n(\mu, \lambda) := (1 - \mu)n + \lambda n(n - 1) . \quad (4.2)$$

Due to [BD] it is known that the critical temperature (and the critical chemical potential $\mu_c(\rho, \lambda)$) are defined, as functions of the total particle density ρ , by two equations:

$$\tilde{p}''(\beta, \mu, \lambda; 0) = 2, \quad \rho = \frac{1}{Z_0(\beta, \mu, \lambda)} \sum_{n=1}^{\infty} n e^{-\beta h_n(\mu, \lambda)}. \quad (4.3)$$

Here

$$\tilde{p}''(\beta, \mu, \lambda; 0) = \frac{2}{Z_0(\beta, \mu, \lambda)} \sum_{n=1}^{\infty} n \frac{e^{-\beta h_n(\mu, \lambda)} - e^{-\beta h_{n-1}(\mu, \lambda)}}{h_{n-1}(\mu, \lambda) - h_n(\mu, \lambda)}. \quad (4.4)$$

and

$$Z_0(\beta, \mu, \lambda) = \sum_{n=0}^{\infty} e^{-\beta h_n(\mu, \lambda)}.$$

If $\varepsilon_x^\omega \neq 0$ and $\lambda > 0$, then by the main Theorem 2.1 (see (2.19), (2.54) and (4.2)) to obtain the equations for the critical temperature and the critical chemical potential we have to replace μ in (4.3) by $\mu - \varepsilon_x^\omega$ and to average over ε_x^ω . This gives, instead of (4.3), the (*gap*) equation:

$$\mathbb{E}[\tilde{p}''(\beta, \mu - \varepsilon^\omega, \lambda; 0)] = 2, \quad (4.5)$$

and equation for density:

$$\rho = \mathbb{E} \left[\frac{1}{Z_0(\beta, \mu - \varepsilon^\omega, \lambda)} \sum_{n=1}^{\infty} n e^{-\beta h_n(\mu - \varepsilon^\omega, \lambda)} \right]. \quad (4.6)$$

The case of $\lambda = 0$ is more subtle, and we begin with it the next subsection.

4.1 Perfect bosons: $\lambda = 0$

Without loss of generality, we can assume that the random ε^ω takes values in the interval $[0, \varepsilon]$. In that case the maximal allowed value for μ (i.e. the *critical value*) is still $\mu_c = 0$, and the critical inverse temperature $\beta_c := \beta_c(\rho, \lambda = 0)$ is given (see (3.34), (3.35)) by:

$$\rho = \mathbb{E} \left[\frac{1}{e^{\beta_c(1+\varepsilon^\omega)} - 1} \right]. \quad (4.7)$$

Remark that, *irrespective* of the distribution of ε^ω , the equation (4.7) implies that the resulting β_c is *lower* than $\ln\left(1 + \frac{1}{\rho}\right)$, which corresponds to the nonrandom case $\varepsilon_x^\omega = 0$, i.e. *disorder enhances* Bose-Einstein condensation. We shall see (Sect.4.3.3) that this is *no longer true* when $\lambda > 0$, and even that the *opposite* holds, if λ is small enough!

Notice that formula (4.7) is in agreement with the general expression found in [L-Z]:

$$\rho = \int \frac{d\bar{\mathcal{N}}(E)}{e^{\beta_c E} - 1}, \quad (4.8)$$

where $\bar{\mathcal{N}}(E)$ is the *integrated* density of states given by

$$\bar{\mathcal{N}}(E) = \text{a.s.-} \lim_{V \rightarrow \infty} \frac{1}{V} \#\{i : E_i^\omega \leq E\}. \quad (4.9)$$

Here $\{E_i^\omega\}_{i \geq 1}$ are the eigenvalues of the one-particle Hamiltonian with a random potential $\{\varepsilon_x^\omega\}_{x \in \Lambda}$:

$$(h_\Lambda^\omega u)(x) := (t_\Lambda u)(x) + \sum_{x \in \Lambda} \varepsilon_x^\omega u(x), \quad x \in \Lambda, \quad u \in \mathfrak{h}(\Lambda), \quad (4.10)$$

for *i.r.* kinetic-energy hopping, see (2.1), (2.10), and $\#\{i : E_i^\omega \leq E\}$ counting the number of the corresponding eigenfunctions (including the *multiplicity*). It is known that for any *ergodic* random potential $\{\varepsilon_x^\omega\}_{x \in \Lambda}$, the limit (4.9) exists *almost surely* (a.s.) and that it is *non-random*, see e.g. [PF]. A contact between formulae (4.7) and (4.8) gives the following

Lemma 4.1 *The integrated density of states is equal to*

$$\bar{\mathcal{N}}(E) = \mathbb{P}[\varepsilon^\omega \leq E - 1] = \mathbb{E}[\theta(E - (1 + \varepsilon^\omega))]. \quad (4.11)$$

Proof: For simplicity we consider the case of a *Bernoulli* random potential $\{\varepsilon_x^\omega\}_{x \in \Lambda}$ such that $\varepsilon_x^\omega = \varepsilon$ with probability p and $\varepsilon_x^\omega = 0$ with probability $1 - p$. (The proof of the general case is similar, but slightly more complicated.) In this special case, the right-hand side of (4.11) equals

$$\mathbb{P}[\varepsilon^\omega \leq E - 1] = \begin{cases} 1 & \text{if } E \geq 1 + \varepsilon, \\ 1 - p & \text{if } 1 \leq E < 1 + \varepsilon, \\ 0 & \text{if } E < 1. \end{cases} \quad (4.12)$$

Clearly, all eigenvalues $\{E_i^\omega\}_{i \geq 1}$ of the Hamiltonian (4.10) belong to the interval $[1, 1 + \varepsilon]$. Since $\dim(\mathfrak{h}(\Lambda)) = V$, one gets $\bar{\mathcal{N}}(E) = 1$, if $E \geq 1 + \varepsilon$. Similarly, $\bar{\mathcal{N}}(E) = 0$, if $E < 1$.

Now suppose that $E \in [1, 1 + \varepsilon)$. Since $\{\varepsilon_x^\omega\}_{x \in \Lambda}$ is the Bernoulli random field, for given $\delta > 0$, there exists $c > 0$ such that with probability $Pr > 1 - \delta$ the number of sites $x \in \Lambda$ with $\varepsilon_x^\omega = \varepsilon$ is in the interval $(pV - c\sqrt{V}, pV + c\sqrt{V})$. Given a configuration for which this is the case, let $\Lambda_\varepsilon \subset \Lambda$ be the set where $\varepsilon_x^\omega = \varepsilon$. Consider the states $\phi \in \mathfrak{h}(\Lambda)$ such that $\phi(x) = 0$, if $x \notin \Lambda_\varepsilon$ and $\sum_{x \in \Lambda} \phi(x) = 0$. Then

$$(h_\Lambda^\omega \phi)(x) = \frac{1}{V} \sum_{y=1}^V (\phi(x) - \phi(y)) + \varepsilon_x^\omega \phi(x) = (\varepsilon + 1)\phi(x), \quad x \in \Lambda_\varepsilon.$$

The space of such eigenfunctions ϕ has dimension $|\Lambda_\varepsilon| - 1$, so that

$$\#\{E_i^\omega > E\} \geq (|\Lambda_\varepsilon| - 1).$$

Since $(\#\{E_i^\omega \leq E\}) + (\#\{E_i^\omega > E\}) = V$, for $V \rightarrow \infty$ we get

$$\bar{\mathcal{N}}(E) \leq 1 - p.$$

Similarly, considering the eigenfunctions with supports concentrated on $\Lambda_\varepsilon^c = \Lambda \setminus \Lambda_\varepsilon$ we obtain

$$\bar{\mathcal{N}}(E) \geq 1 - p.$$

Together with (4.12) these estimates give the proof of (4.11). \square

The relations (4.11) show that the formulae (4.7) and (4.8) are equivalent. For details of a general statement see e.g. [PF] Ch.II.5 .

4.2 Discrete random potential and $\lambda > 0$

We now consider the case with interaction $\lambda > 0$, and first assume that the probability distribution of ε_x^ω is *discrete*.

A particularly simple case corresponds to the *hard-core* boson limit $\lambda = +\infty$, see Section 3. Then by (3.21) the equations for the critical value of the inverse temperature $\beta_c := \beta_c(\rho) = \beta_c(\rho, \lambda = +\infty)$ for a given density ρ , reduce to the system:

$$\mathbb{E} \left[\frac{\tanh \beta(\mu - \varepsilon^\omega - 1)/2}{\mu - \varepsilon^\omega - 1} \right] = 1 \quad (4.13)$$

and

$$\rho = \frac{1}{2} + \frac{1}{2} \mathbb{E} \left[\tanh \frac{1}{2} \beta(\mu - \varepsilon^\omega - 1) \right]. \quad (4.14)$$

The last equation (4.14) implies that for the hard-core interaction the total particle density has the estimate: $\rho \leq 1$.

4.2.1 Bernoulli random potential in the hard-core limit $\lambda = +\infty$.

A special case of a discrete distribution is the Bernoulli distribution, where $\varepsilon_x^\omega = \varepsilon$ with probability p and $\varepsilon_x^\omega = 0$ with probability $1 - p$. We first consider the case $\lambda = +\infty$. The equations (4.13) and (4.14) then read,

$$F_{p,\varepsilon}(\beta = \beta_c, \mu) := p \frac{\tanh \frac{1}{2} \beta_c(\mu - \varepsilon - 1)}{\mu - \varepsilon - 1} + (1 - p) \frac{\tanh \frac{1}{2} \beta_c(\mu - 1)}{\mu - 1} = 1 \quad (4.15)$$

and

$$G_{p,\varepsilon}(\beta = \beta_c, \mu) := \frac{1}{2} + \frac{1}{2} \left[p \tanh \frac{1}{2} \beta_c(\mu - \varepsilon - 1) + (1 - p) \tanh \frac{1}{2} \beta_c(\mu - 1) \right] = \rho. \quad (4.16)$$

Here a *new phenomenon* occurs for density $\rho = 1 - p$. To see this, we consider first a particular case of $p = 1/2$. Then $\rho = 1/2$, and by (4.16) we obtain, that the only possible solution for the corresponding chemical potential is $\mu(\rho = 1/2) := \mu(\rho = 1/2, \lambda = +\infty) = 1 + \varepsilon/2$. Inserting this value of μ into (4.15) we get for the critical temperature:

$$\tanh \frac{\beta_c \varepsilon}{4} = \frac{1}{2} \varepsilon.$$

This equation obviously has *no solution* for $\varepsilon \geq 2$. Therefore, there is *no* Bose-Einstein condensation for Bernoulli random potential, if $p = \rho = 1/2$, and ε is greater than some *critical* value: $\varepsilon_{cr} = 2$.

One can check that the same phenomenon occurs for $p \neq 1/2$ and for densities $\rho = 1 - p$, if ε is *large* enough, but now the reasoning is more delicate. First of all, by (4.15) and $\tanh u \leq u$ we see that in any case there is a *lower bound* on the inverse critical temperature:

$$\beta_c \geq 2. \quad (4.17)$$

Now assume that $p < 1/2$, i.e. $\rho > 1/2$. From (4.16) it then follows that for any ε one has

$$0 < \mu - 1 - \frac{1}{2} \varepsilon. \quad (4.18)$$

Indeed, if we suppose that $0 \leq \mu - 1 \leq \varepsilon/2$, then $\tanh \frac{1}{2}\beta_c(\mu - 1) \leq \tanh \frac{1}{2}\beta_c(1 + \varepsilon - \mu)$ and hence, by (4.16), we get

$$\begin{aligned} 2\rho - 1 &= p \tanh \frac{1}{2}\beta_c(\mu - \varepsilon - 1) + (1 - p) \tanh \frac{1}{2}\beta_c(\mu - 1) \\ &\leq (1 - 2p) \tanh \frac{1}{2}\beta_c(\varepsilon + 1 - \mu) < 1 - 2p, \end{aligned}$$

contradicting our assumption $\rho = 1 - p$, if β_c exists and is finite.

Now notice that (4.16) with $\rho = 1 - p$ is equivalent to

$$\frac{1 - \tanh \frac{1}{2}\beta_c(\varepsilon + 1 - \mu)}{1 - \tanh \frac{1}{2}\beta_c(\mu - 1)} = \frac{1 - p}{p}. \quad (4.19)$$

The left-hand side of (4.19) can be estimated from below as

$$\frac{1 - \tanh \frac{1}{2}\beta_c(\varepsilon + 1 - \mu)}{1 - \tanh \frac{1}{2}\beta_c(\mu - 1)} = \frac{e^{\beta_c(\mu - 1 - \varepsilon/2)} + e^{-\beta_c\varepsilon/2}}{e^{-\beta_c(\mu - 1 - \varepsilon/2)} + e^{-\beta_c\varepsilon/2}} > e^{\beta_c(\mu - 1 - \varepsilon/2)}.$$

Together with (4.17) this yield an upper bound for (4.18):

$$0 < \mu - 1 - \frac{1}{2}\varepsilon < \frac{1}{\beta_c} \ln \frac{1 - p}{p} \leq \frac{1}{2} \ln \frac{1 - p}{p} < \frac{1 - 2p}{2p}. \quad (4.20)$$

But (4.20) implies that (4.15) has *no* solution β_c , since for *large* ε we obtain

$$\begin{aligned} p \frac{\tanh \frac{1}{2}\beta_c(\mu - \varepsilon - 1)}{\mu - \varepsilon - 1} + (1 - p) \frac{\tanh \frac{1}{2}\beta_c(\mu - 1)}{\mu - 1} &< \\ \frac{p}{\varepsilon + 1 - \mu} + \frac{1 - p}{\mu - 1} &< \frac{p}{\varepsilon/2 - (1 - 2p)/2p} + \frac{1 - p}{\varepsilon/2} < 1. \end{aligned} \quad (4.21)$$

We assumed that $p < 1/2$. Therefore by (4.21), our conclusion is true, in fact, for

$$\varepsilon \geq 1/p \geq 2 = \varepsilon_{cr}. \quad (4.22)$$

The same result follows in the case $p \geq 1/2$, if we interchange p and $1 - p$ and $\mu - 1$ and $1 + \varepsilon - \mu$ in the above argument.

Next we show that for any *other* $\rho \in (0, 1)$, i.e. for any $\rho \neq 1 - p$, the critical $\beta_c(\rho) < +\infty$, i.e. for these densities one always has the Bose-Einstein condensation at low temperatures.

To this end suppose that there is $\rho^* \in (0, 1)$ such that $\rho^* \neq 1 - p$, but $\lim_{\rho \rightarrow \rho^*} \beta_c(\rho) = +\infty$. Then the left-hand side of (4.15) converges to

$$\lim_{\beta \rightarrow \infty} F_{p,\varepsilon}(\beta, \mu) = M_p(\mu, \varepsilon) := \frac{p}{|\mu - \varepsilon - 1|} + \frac{1 - p}{|\mu - 1|}. \quad (4.23)$$

The number of solutions of equation (4.15) in the limit $\lim_{\rho \rightarrow \rho^*} \beta_c(\rho) = +\infty$ depends on the value of $\varepsilon > 0$, but two singular points $\mu = 1$ and $\mu = 1 + \varepsilon$ of the function (4.23) ensure (for nontrivial values of the probability: $p \neq 0$ and $p \neq 1$) that there are always at least *two solutions*: $\mu_1(\varepsilon) < 1$ and $\mu_2(\varepsilon) > 1 + \varepsilon$ of equation

$$M_p(\mu, \varepsilon) = 1. \quad (4.24)$$

If $\lim_{\rho \rightarrow \rho^*} \beta_c(\rho) = +\infty$, then for these two cases the equation (4.16) implies:

$$\begin{aligned}\rho^* &= \lim_{\rho \rightarrow \rho^*} G_{p,\varepsilon}(\beta_c(\rho), \mu_1(\varepsilon)) = 0 , \\ \rho^* &= \lim_{\rho \rightarrow \rho^*} G_{p,\varepsilon}(\beta_c(\rho), \mu_2(\varepsilon)) = 1 .\end{aligned}$$

This contradicts our assumptions on ρ^* and makes impossible the hypothesis $\lim_{\rho \rightarrow \rho^*} \beta_c(\rho) = +\infty$.

Notice that the function $M_p(\mu, \varepsilon)$ has a *minimum* $\bar{\mu}(\varepsilon) \in (1, 1 + \varepsilon)$. If $M_p(\bar{\mu}(\varepsilon), \varepsilon) < 1$ (which is equivalent to $\varepsilon > \varepsilon_p := 1 + 2\sqrt{p(1-p)}$), then equation (4.24) has *two* complementary solutions $\mu_{\mp}(\varepsilon)$:

$$\mu_{\mp}(\varepsilon) = \frac{\varepsilon + 3}{2} - p \mp \sqrt{\left(\frac{\varepsilon - 1}{2}\right)^2 - p(1-p)} , \quad (4.25)$$

such that

$$1 < \mu_-(\varepsilon) < \bar{\mu}(\varepsilon) < \mu_+(\varepsilon) < 1 + \varepsilon .$$

If $\lim_{\rho \rightarrow \rho^*} \beta_c(\rho) = +\infty$, then for these two solutions equation (4.16) implies:

$$\rho^* = \lim_{\rho \rightarrow \rho^*} G_{p,\varepsilon}(\beta_c(\rho), \mu_{\mp}(\varepsilon)) = 1 - p ,$$

This again contradicts our assumption about ρ^* , and thus proves the assertion: $\beta_c(\rho) < +\infty$ for any $\rho \neq 1 - p$.

Notice that by (4.25) the equation $M_p(\bar{\mu}(\varepsilon), \varepsilon) = 1$ has a unique solution $\varepsilon = \varepsilon_p \leq \varepsilon_{cr} = 2$, and one obtains $M_p(\bar{\mu}(\varepsilon), \varepsilon) > 1$ for all $\varepsilon < \varepsilon_p$, which excludes complementary solutions $\mu_{\mp}(\varepsilon)$. On the other hand, if

$$\varepsilon > \varepsilon_{cr} = \max_p \varepsilon_p = \varepsilon_{p=1/2} , \quad (4.26)$$

there are *always* complementary solutions (4.25). This may *restrict* the values of ρ , for which we have bounded critical $\beta_c(\rho)$, to a certain domain of densities.

To this end we consider first the ρ -independent equation (4.15). Notice that $F_{p,\varepsilon}(\beta, \mu)$ is a monotonously increasing function of β , so there is a *unique* solution $\tilde{\beta}_c(\mu)$ of equation (4.15) for a given μ , *if* there is one.

Since $(\tanh u)/u \leq 1$, then the left-hand side of (4.15) is *less* than 1, for $\beta \leq 2$. On the other hand, as $\beta \rightarrow \infty$, the left-hand side of (4.15) converges to $M_p(\mu, \varepsilon)$. Since the function (4.23) is singular at $\mu = 1$ and $\mu = 1 + \varepsilon$, a solution $2 < \tilde{\beta}_c(\mu) < +\infty$ for a certain μ always exists, and the set of those μ is defined by the condition:

$$S_{p,\varepsilon} := \{\mu \in \mathbb{R}^1 : \lim_{\beta \rightarrow \infty} F_{p,\varepsilon}(\beta, \mu) = M_p(\mu, \varepsilon) \geq 1\} \quad (4.27)$$

By (4.23) the set (4.27) for $\varepsilon > 0$ is a *compact* in \mathbb{R}_+^1 . If there are no complementary solutions $\mu_{\mp}(\varepsilon)$, this compact is *connected*, but if

$$\varepsilon > \varepsilon_{cr} . \quad (4.28)$$

it contains two domains separated by a *gap*:

$$I(\varepsilon, p) := (\mu_-(\varepsilon), \mu_+(\varepsilon)),$$

see (4.25). The gap $I(\varepsilon, p) \subset (1, 1 + \varepsilon)$. There is no solutions $\tilde{\beta}_c(\mu)$ for $\mu \in I(\varepsilon, p)$ and for

$$\mu < (\varepsilon + 1)/2 - \sqrt{((\varepsilon - 1)/2)^2 - \varepsilon(1 - p)} ,$$

or for

$$\mu > (\varepsilon + 3)/2 + \sqrt{((\varepsilon + 1)/2)^2 - \varepsilon(1 - p)} .$$

Hence, for large ε (4.28) the set $S_{p,\varepsilon}$ is a union of two (separated by the gap $I(\varepsilon, p)$) bounded domains, which are vicinities of singular points $\mu = 1$ and $\mu = 1 + \varepsilon$. It is in fact **not** the

To understand, how the gap in the chemical potential for solution $\tilde{\beta}_c(\mu)$ modify the behaviour of $\beta_c(\rho)$, we have to consider the ρ -dependent equation (4.16). Notice that from (4.16) one obtains $\hat{\beta}_c(\mu, \rho)$ as a function of two variables. Therefore, $\beta_c(\rho)$ is a solution of equation:

$$\tilde{\beta}_c(\mu) = \hat{\beta}_c(\mu, \rho) , \quad (4.29)$$

which in fact connects μ and ρ : $\bar{\mu}(\rho)$, i.e. $\beta_c(\rho) = \tilde{\beta}_c(\bar{\mu}(\rho)) = \hat{\beta}_c(\bar{\mu}(\rho), \rho)$.

Clearly, the left-hand side $G_{p,\varepsilon}(\beta, \mu)$ is increasing in μ and it tends to 0 as $\mu \rightarrow -\infty$ and to 1 as $\mu \rightarrow +\infty$. Excluding $\rho = 0$ or 1, there is therefore a *unique* solution $\mu(\beta, \rho)$ of (4.16) for each value of β . As $\beta \rightarrow 0$, $G_{p,\varepsilon}(\beta, \mu)$ tends to 1/2 at constant μ . Therefore, if $\rho \neq 1/2$

$$\lim_{\beta \rightarrow 0} \mu(\beta, \rho) = \pm\infty ,$$

depending on whether $\rho > 1/2$ or $\rho < 1/2$.

On the other hand, in the limit $\beta \rightarrow \infty$, we have that $G_{p,\varepsilon}(\beta, \mu)$: (a) tends to 0, if $\mu < 1$; (b) to $(1 - p)/2$, if $\mu = 1$; (c) to $1 - p$, if $1 < \mu < 1 + \varepsilon$; (d) to $1 - p/2$, if $\mu = 1 + \varepsilon$, and (e) to 1, if $\mu > 1 + \varepsilon$.

The (a) – (e) give relation between ρ and μ for large β : if $0 < \rho < 1 - p$, we must have $\mu(\beta, \rho) \rightarrow 1$ and, if $1 - p < \rho < 1$, we obtain $\mu(\beta, \rho) \rightarrow 1 + \varepsilon$, for $\beta \rightarrow \infty$. At $\rho = 1 - p$, we have to use the representation (4.19), that yields

$$\mu(\beta, \rho = 1 - p) = 1 + \frac{1}{2}\varepsilon - \frac{1}{2\beta} \ln \frac{p}{1 - p} + o(\beta^{-1}) , \quad (4.30)$$

if β is large. In particular, this justifies the remark (4.22) above about $\varepsilon_{\text{cr}} = 2$, since $1 + \varepsilon/2$ lies in the gap $I(\varepsilon, p)$ only if $\varepsilon \geq 2 = \varepsilon_{\text{cr}}$, see (4.25).

Hence, it follows that for $\rho \neq 1 - p$ two functions of μ corresponding to solutions (4.29) of equations (4.15), (4.16) must intersect. On the other hand, (4.22) proves that they can not intersect for $\rho = 1 - p$, if $\varepsilon > \varepsilon_{\text{cr}}$. In fact, we can derive *upper* bounds for $\beta_c(\rho)$ in the case $\rho \neq 1 - p$ and $|\rho - 1 + p|$ small.

To this end *we first consider the case* $\rho > 1 - p$. Let us assume $p \leq 1/2$. (The case $p > 1/2$ can be studied similarly.) Writing $\rho = 1 - p + \delta/2$ we present the equation (4.16) in the form

$$p \tanh \frac{1}{2}\beta_c(\varepsilon + 1 - \mu) = (1 - p) \tanh \frac{1}{2}\beta_c(\mu - 1) + 2p - 1 - \delta . \quad (4.31)$$

Identity (4.31) implies that $\mu > 1 + \varepsilon/2$, since otherwise we get a contradiction:

$$\begin{aligned} 1 - 2p + \delta &= -p \tanh \frac{1}{2}\beta_c(\varepsilon + 1 - \mu) + (1 - p) \tanh \frac{1}{2}\beta_c(\mu - 1) \leq \\ &-p \tanh \frac{1}{2}\beta_c(\varepsilon + 1 - \mu) + (1 - p) \tanh \frac{1}{2}\beta_c(\varepsilon + 1 - \mu) \leq 1 - 2p . \end{aligned}$$

On the other hand, for $\varepsilon \geq 1$, one gets the upper limit $\mu < \varepsilon + 1$. Indeed, if we suppose the opposite: $\mu \geq \varepsilon + 1$, then (4.16) and the general fact that $\beta_c \geq 2$ (see (4.17)) yield

$$\begin{aligned} 1 - 2p + \delta &= p \tanh \frac{1}{2} \beta_c (\mu - \varepsilon - 1) + (1 - p) \tanh \frac{1}{2} \beta_c (\mu - 1) \\ &\geq (1 - p) \tanh \frac{1}{2} \beta_c (\mu - 1) \geq (1 - p) \tanh \varepsilon. \end{aligned}$$

But this is impossible for (large) ε verifying:

$$\varepsilon > \frac{1}{2} \ln \frac{2 - 3p + \delta}{p - \delta}. \quad (4.32)$$

Therefore, we obtain for μ the *lower* and *upper* bounds:

$$1 + \varepsilon/2 < \mu < 1 + \varepsilon. \quad (4.33)$$

Now identity (4.31), together with the bounds (4.33), inequality $\tanh(u) > 1 - 2e^{-2u}$ and $\beta_c \geq 2$ (see (4.17)), yields the estimates:

$$\begin{aligned} 1 - \frac{\delta}{p} - \frac{2}{p} e^{-\varepsilon} &< \tanh \frac{1}{2} \beta_c (\varepsilon + 1 - \mu) < 1 - \frac{\delta}{p}. \quad (4.34) \\ 1 &> \frac{p - \delta - 2e^{-\varepsilon}}{\varepsilon + 1 - \mu} + (1 - p) \frac{1 - 2e^{-\varepsilon}}{\mu - 1} > \frac{\beta_c (p - \delta - 2e^{-\varepsilon})}{\ln(2p/\delta)} \end{aligned}$$

and hence,

$$\beta_c < \frac{1}{p - \delta - 2e^{-\varepsilon}} \ln(2p/\delta). \quad (4.35)$$

The upper bound (4.35) holds for example, if $\delta < p/2$ and $\varepsilon > \ln(4/p)$.

Now *we consider the case* $\rho < 1 - p$ and suppose $p \leq 1/2$, since $p > 1/2$ can be studied similarly. Then we write: $\rho = 1 - p - \delta/2$. Equation (4.16) now reads as

$$(1 - p) \tanh \frac{1}{2} \beta_c (\mu - 1) = p \tanh \frac{1}{2} \beta_c (1 + \varepsilon - \mu) + 1 - 2p - \delta. \quad (4.36)$$

An argument similar to the case $\rho > 1 - p$ shows that

$$1 < \mu < 1 + \varepsilon, \quad (4.37)$$

if ε is large enough and $\delta < 1 - p$. Indeed, if we suppose the opposite: $\mu \geq 1 + \varepsilon$, then

$$1 - 2p - \delta \geq (1 - p) \tanh \frac{1}{2} \beta_c (\mu - 1) \geq (1 - p) \tanh \varepsilon,$$

which is impossible for

$$\varepsilon > \frac{1}{2} \ln \frac{2 - 3p - \delta}{p + \delta}.$$

Similarly, if we suppose that $\mu \leq 1$, then (4.36) implies

$$0 > p \tanh \frac{1}{2} \beta_c (1 + \varepsilon - \mu) + 1 - 2p - \delta > p \tanh \varepsilon + (1 - 2p - \delta),$$

which is impossible if $\delta < 1 - 2p$, or if $1 - 2p \leq \delta < 1 - p$ and

$$\varepsilon > \frac{1}{2} \ln \frac{3p - 1 + \delta}{1 - p - \delta} .$$

Now, (4.36) and (4.37) imply that

$$\tanh \frac{1}{2} \beta_c (\mu - 1) < 1 - \frac{\delta}{1 - p} . \quad (4.38)$$

In the case $\mu \geq 1 + \frac{1}{2} \varepsilon$ this yields immediately the upper bound :

$$\beta_c < \frac{2}{\varepsilon} \ln \frac{2(1 - p)}{\delta} . \quad (4.39)$$

On the other hand, if $1 < \mu < 1 + \varepsilon/2$, then by (4.36) and $\beta_c \geq 2$ we obtain

$$\begin{aligned} (1 - p) \tanh \frac{1}{2} \beta_c (\mu - 1) &> p \tanh \frac{1}{4} \beta_c \varepsilon + 1 - 2p - \delta > \\ p \tanh \frac{1}{2} \varepsilon + 1 - 2p - \delta &> p(1 - 2e^{-\varepsilon}) + 1 - 2p - \delta = 1 - p - \delta - 2pe^{-\varepsilon} . \end{aligned} \quad (4.40)$$

Taking into account equation (4.15) and estimates (4.38), (4.40), we get

$$1 > \frac{1 - p - \delta - 2pe^{-\varepsilon}}{\mu - 1} > \beta_c \frac{1 - p - \delta - 2pe^{-\varepsilon}}{\ln(2(1 - p)/\delta)} ,$$

that gives the upper bound:

$$\beta_c < \frac{1}{1 - p - \delta - 2pe^{-\varepsilon}} \ln \frac{2(1 - p)}{\delta} . \quad (4.41)$$

4.2.2 Bernoulli random potential for the case $\lambda < +\infty$.

We assume in this subsection that $\lambda > \varepsilon + 1$. If the repulsion is very large ($\lambda \gg \varepsilon + 1$), the analysis for $\rho < 1$ is then almost the same as above for $\lambda = +\infty$, whereas for $\rho \geq 1$, which is possible only for finite λ , one needs some more arguments.

Here we start with the estimate the *first-order* correction in λ^{-1} to the value of $\varepsilon_{\text{cr}}(\lambda = +\infty) = 2$. With this accuracy the equations (4.5) and (4.6) can be approximated correspondingly by

$$\begin{aligned} p \left(\frac{\tanh \frac{1}{2} \beta (\mu - \varepsilon - 1)}{\mu - \varepsilon - 1} + \frac{1}{2\lambda + \varepsilon + 1 - \mu} \frac{e^{-\beta(1 + \varepsilon - \mu)/2}}{\cosh \frac{1}{2} \beta (1 + \varepsilon - \mu)} \right) \\ + (1 - p) \left(\frac{\tanh \frac{1}{2} \beta (\mu - 1)}{\mu - 1} + \frac{1}{2\lambda + 1 - \mu} \frac{e^{\beta(\mu - 1)/2}}{\cosh \frac{1}{2} \beta (\mu - 1)} \right) = 1 , \end{aligned} \quad (4.42)$$

and by (4.16) as above.

To see this, note that if $\rho < 1$, the dominant contribution in (4.6) must come from the $n = 1$ term, i.e. we must have $h_1 < h_2$, so $\mu < 1 + 2\lambda + \varepsilon$. The other terms in (4.6) are then exponentially small and can be neglected, which leads again to (4.16).

Now, because of the presence of $e^{-\beta h_1}$ in the $n = 2$ term of (4.4), it cannot be neglected in (4.5) and we obtain:

$$\frac{2p}{1 + e^{-\beta(1+\varepsilon-\mu)}} \left\{ \frac{e^{-\beta(1+\varepsilon-\mu)} - 1}{\mu - 1 - \varepsilon} + 2 \frac{e^{-\beta(1+\varepsilon-\mu)}}{1 + 2\lambda + \varepsilon - \mu} \right\} + \frac{2(1-p)}{1 + e^{-\beta(1-\mu)}} \left\{ \frac{e^{-\beta(1-\mu)} - 1}{\mu - 1} + 2 \frac{e^{-\beta(1-\mu)}}{1 + 2\lambda - \mu} \right\} = 2 ,$$

which is the same as (4.42).

Similar to (4.23) the gap equation for $1 < \mu < 1 + \varepsilon$ can be obtained from (4.42) in the limit $\beta \rightarrow \infty$:

$$\frac{p}{\varepsilon + 1 - \mu} + (1-p) \left(\frac{1}{\mu - 1} + \frac{2}{2\lambda + 1 - \mu} \right) = 1. \quad (4.43)$$

If $\rho = 1 - p$, then by (4.16) and (4.30) we again obtain the limit: $\mu \rightarrow 1 + \frac{1}{2}\varepsilon$ for $\beta \rightarrow \infty$. Inserting this limit into (4.43) we obtain

$$\frac{2}{\varepsilon} + \frac{2(1-p)}{2\lambda - \frac{1}{2}\varepsilon} = 1. \quad (4.44)$$

Hence, by the reasoning similar to those after (4.30), we obtain the critical value of the Bernoulli random potential $\varepsilon_{\text{cr}}(\lambda)$ the expression:

$$\varepsilon_{\text{cr}}(\lambda) \approx \frac{2}{1 - (1-p)/\lambda} = 2 + 2(1-p)/\lambda + \dots , \quad (4.45)$$

which takes into account that λ is large but *finite*.

Another observation, which is related to the finiteness of λ , concerns the value $\beta_c(\rho = 1)$. For hard-core bosons the arguments in the Sect.4.2.1 show that this value is *infinite* and the corresponding values of the chemical potential must be greater than $1 + \varepsilon$, see (4.6). Now for finite λ and $\mu > 1 + \varepsilon$ the limit of (4.42), when $\beta \rightarrow \infty$, reads as:

$$p \left(\frac{1}{\mu - \varepsilon - 1} + \frac{2}{2\lambda + 1 + \varepsilon - \mu} \right) + (1-p) \left(\frac{1}{\mu - 1} + \frac{2}{2\lambda + 1 - \mu} \right) = 1. \quad (4.46)$$

If $\rho \geq 1$, then we need to reconsider the density equation (4.6), which has the form:

$$\rho = p \frac{\sum_{n=1}^{\infty} n e^{-\beta h_n(\mu-\varepsilon,\lambda)}}{\sum_{n=0}^{\infty} e^{-\beta h_n(\mu-\varepsilon,\lambda)}} + (1-p) \frac{\sum_{n=1}^{\infty} n e^{-\beta h_n(\mu,\lambda)}}{\sum_{n=0}^{\infty} e^{-\beta h_n(\mu,\lambda)}}. \quad (4.47)$$

Notice that if $\beta \rightarrow +\infty$, then by (4.2) and (4.47) one obtains the following limits: $\rho \rightarrow 1$, when $\mu \in (1 + \varepsilon, 1 + 2\lambda)$, $\rho \rightarrow 2 - p$, when $\mu \in (1 + 2\lambda, 1 + 2\lambda + \varepsilon)$, and $\rho \rightarrow 2$, when $\mu \in (1 + 2\lambda + \varepsilon, 1 + 4\lambda)$.

Therefore, at $\rho = 1$ for large β we can ignore in (4.47) the terms higher than h_2 , see (4.2),

and write in this limit:

$$\begin{aligned}
1 &\approx p \left\{ \frac{e^{-\beta(1+\varepsilon-\mu)} + 2e^{-2\beta(1+\lambda+\varepsilon-\mu)}}{1 + e^{-\beta(1+\varepsilon-\mu)} + e^{-2\beta(1+\lambda+\varepsilon-\mu)}} \right\} \\
&\quad + (1-p) \left\{ \frac{e^{-\beta(1-\mu)} + 2e^{-2\beta(1+\lambda-\mu)}}{1 + e^{-\beta(1-\mu)} + e^{-2\beta(1+\lambda-\mu)}} \right\} \\
&= p \left\{ \frac{1 + 2e^{-\beta(1+2\lambda+\varepsilon-\mu)}}{1 + e^{-\beta(\mu-1-\varepsilon)} + e^{-\beta(1+2\lambda+\varepsilon-\mu)}} \right\} \\
&\quad + (1-p) \left\{ \frac{1 + 2e^{-\beta(1+2\lambda-\mu)}}{1 + e^{-\beta(\mu-1)} + e^{-\beta(1+2\lambda-\mu)}} \right\} \\
&\approx 1 + p \left(e^{-\beta(1+2\lambda+\varepsilon-\mu)} - e^{-\beta(\mu-1-\varepsilon)} \right) \\
&\quad + (1-p) \left(e^{-\beta(1+2\lambda-\mu)} - e^{-\beta(\mu-1)} \right).
\end{aligned} \tag{4.48}$$

This yields

$$e^{2\beta\mu} \approx e^{2\beta(1+\lambda)} \frac{1-p + pe^{\beta\varepsilon}}{1-p + pe^{-\beta\varepsilon}} \approx \frac{p}{1-p} e^{2\beta(1+\lambda+\frac{1}{2}\varepsilon)}.$$

The chemical potential defined by equation (4.47) therefore tends (for $\rho = 1$) to $1 + \lambda + \frac{1}{2}\varepsilon$ as $\beta \rightarrow +\infty$.

Therefore, inserting this into (4.46) we obtain the estimate for the value of *repulsion* $\lambda_{c,1}$ that ensures that $\beta_c(\rho = 1) = +\infty$ in the presence of the random Bernoulli potential:

$$\lambda_{c,1}(\varepsilon) = \frac{1}{2} \left[3 + \sqrt{9 + 2\varepsilon(1 - 2p + \frac{1}{2}\varepsilon)} \right]. \tag{4.49}$$

Remark 4.1 *In the absence of disorder, i.e. if $\varepsilon = 0$, the critical value of lambda is $\lambda_{c,1} = 3$ as opposed to $\lambda_1 = \frac{1}{2}(3 + \sqrt{8})$ as suggested in [BD]. The reason is the same as above for ε_{cr} , namely, the graph of $\mu(\beta, \rho)$ at $\rho = 1$ tends to $1 + \lambda$ as $\beta \rightarrow +\infty$ and this lies in the gap only if $\lambda \geq 3$. Similarly, the next critical values are given by*

$$\lambda_{c,k}(\varepsilon = 0) = 2k + 1. \tag{4.50}$$

Remark 4.2 *In Sect.4.2.1 we notice a new phenomenon specific for the random case: divergence of β_c at $\rho = 1 - p$ for hard-core bosons, cf. Figure 1 for $p = 1/2$. Instead of fixing λ , fixing $\varepsilon > 2$ it follows from (4.44) that there is a critical value of the repulsion $\lambda_{c,1-p}(\varepsilon)$ (instead of ε as in (4.45)) so that $\beta_c(\rho = 1 - p)$ diverges for $\lambda \geq \lambda_{c,1-p}(\varepsilon)$ in the presence of the random Bernoulli potential:*

$$\lambda_{c,1-p}(\varepsilon) = \frac{\varepsilon}{4} + \frac{\varepsilon(1-p)}{\varepsilon - 2}. \tag{4.51}$$

This critical value is not evident from Figure 1 as $\varepsilon = 2$.

Remark 4.3 *In Sect.4.1 we remarked that the critical temperature for free bosons increases due to disorder. We also remarked that for the interacting case this is a more subtle matter, since it depends on the value of repulsion. For large repulsions close to e.g. $\lambda_{c,1}(\varepsilon = 0) = 3$, we get by (4.49) that*

$$\beta_c(\rho = 1; \lambda = 3, \varepsilon > 0) < \beta_c(\rho = 1; \lambda = 3, \varepsilon = 0) = +\infty. \tag{4.52}$$

This lowering of $\beta_c(\rho = 1)$ can be explained intuitively as follows. At density $\rho = 1$, there is one particle per site. If $\varepsilon = 0$ there is a penalty for a particle to jump to an already occupied site, so the preferred state is where the particles are at fixed sites, which is almost an eigenstate of the number operators n_x for each site. This prevents Bose condensation. (This argument was presented also in [BD].) However, if $\varepsilon > 0$, then the lattice splits into two parts with energies 0 and ε , and a particle jumping from a site with energy ε to a site with energy 0 loses an energy ε , which counteracts the gain of λ . This creates more freedom of movement and therefore promotes Bose condensation. On the other hand, for a fractional value of the ρ in the neighbourhood of $\rho = 1 - p$, the critical temperature decreases with increasing ε as can be seen from Figure 1.

Now consider the case $\rho > 1$. From equation (4.47) we see that at fixed $\rho \in (1, 2 - p)$, $\mu \rightarrow 1 + 2\lambda$ and for $\rho \in (2 - p, 2)$, $\mu \rightarrow 1 + 2\lambda + \varepsilon$ as $\beta \rightarrow \infty$.

For the case $\rho = 2 - p$, we have to expand (4.47), as above for $\rho = 1$, see (4.48), but to take into account that $\mu \in (1 + 2\lambda, 1 + 2\lambda + \varepsilon)$:

$$\begin{aligned} \rho &\approx p \left\{ \frac{1 + 2e^{-\beta(1 + 2\lambda + \varepsilon - \mu)}}{1 + e^{-\beta(\mu - 1 - \varepsilon)} + e^{-\beta(1 + 2\lambda + \varepsilon - \mu)}} \right\} \\ &\quad + (1 - p) \left\{ \frac{e^{\beta(1 + 2\lambda - \mu)} + 2}{1 + e^{\beta(1 + 2\lambda - \mu)} + e^{-2\beta(\mu - 1 - \lambda)}} \right\} \\ &\approx 2 - p + p \left(e^{-\beta(1 + \varepsilon + 2\lambda - \mu)} - e^{-\beta(\mu - 1 - \varepsilon)} \right) - \\ &\quad (1 - p)e^{-\beta(\mu - 1 - 2\lambda)} - 2(1 - p)e^{-2\beta(\mu - 1 - \lambda)}. \end{aligned} \quad (4.53)$$

This yields that $e^{-\beta(\mu - 1 - 2\lambda)} \approx e^{-\beta(1 + \varepsilon + 2\lambda - \mu)}p/(1 - p)$ for large β , i.e. $\mu \rightarrow 1 + 2\lambda + \frac{1}{2}\varepsilon$, if $\rho = 2 - p$ and $\beta \rightarrow \infty$.

For $\mu \approx 1 + 2\lambda + \frac{1}{2}\varepsilon$, one has $h_1(\mu - \varepsilon, \lambda) < h_2(\mu - \varepsilon, \lambda)$. So that the p -terms in (4.42) are unchanged, but $h_1(\mu, \lambda) > h_2(\mu, \lambda) < h_3(\mu, \lambda)$, if $\lambda > \varepsilon/4$, which corresponds to our initial hypothesis about the value of repulsion: $\lambda > 1 + \varepsilon$. Hence, the $(1 - p)$ -terms are now dominated for large β by $n = 2$ and (4.42) read as

$$\begin{aligned} &\frac{p}{1 + e^{-\beta(1 + \varepsilon - \mu)}} \left\{ \frac{e^{-\beta(1 + \varepsilon - \mu)} - 1}{\mu - 1 - \varepsilon} + 2 \frac{e^{-\beta(1 + \varepsilon - \mu)}}{1 + 2\lambda + \varepsilon - \mu} \right\} \\ &+ \frac{1 - p}{e^{-\beta(1 - \mu)} + e^{-2\beta(1 - \mu + \lambda)}} \left\{ 2 \frac{e^{-2\beta(1 - \mu + \lambda)} - e^{-\beta(1 - \mu)}}{\mu - 1 - 2\lambda} + 3 \frac{e^{-2\beta(1 - \mu + \lambda)}}{1 + 4\lambda - \mu} \right\} \approx 1, \end{aligned}$$

In the limit $\beta \rightarrow \infty$ we obtain from this relation the gap equation

$$\begin{aligned} &p \left(\frac{1}{\mu - 1 - \varepsilon} + \frac{2}{1 + \varepsilon + 2\lambda - \mu} \right) + \\ &(1 - p) \left(\frac{2}{\mu - 1 - 2\lambda} + \frac{3}{1 + 4\lambda - \mu} \right) = 1. \end{aligned} \quad (4.54)$$

Inserting $\mu = 1 + 2\lambda + \frac{1}{2}\varepsilon$ into (4.54) leads to

$$\frac{1}{2}\varepsilon^2 - (2\lambda - 1 + 2p)\varepsilon + 8\lambda = 0. \quad (4.55)$$

Solutions of (4.55) are:

$$\varepsilon_{\text{cr}, \pm}^{(2)} = (2\lambda - 1 + 2p) \pm \sqrt{(2\lambda - 1 + 2p)^2 - 16\lambda}. \quad (4.56)$$

Hence, there is a solution that for large λ has the form:

$$\varepsilon_{\text{cr}}^{(2)}(\lambda) = 4 \left(1 + \frac{1 - 2p}{2\lambda} \right) + \dots, \quad (4.57)$$

or other way around, for a given ε we have:

$$\lambda_{c,\rho=2-p}(\varepsilon) = \frac{2(2p - 1)}{(\varepsilon - 4)}. \quad (4.58)$$

Clearly, this critical value only applies if $\varepsilon > 4$ and $p > 1/2$. The top graph of Figure 1 illustrates this behaviour at $\rho = 1.5$ for $\varepsilon = 4.5$ and $\lambda = 10$.

The critical $\beta_c(\rho)$ for the Bernoulli distribution with $p = 1/2$ and $\varepsilon = 2$ is shown in Figure 1 for a number of values of λ . Notice in particular that $\varepsilon < \varepsilon_{\text{cr}}(\lambda)$, see (4.45), for all finite λ , so that $\beta_c(\rho = 1/2) < +\infty$.

Also, for $\lambda = 3.3$, one obtains $\beta_c(\rho = 1) < +\infty$ because $3.3 < \lambda_{c,1}(\varepsilon = 2) = (3 + \sqrt{13})/2$, see (4.49).

Figure 1: β_c as a function of the density ρ in the case of averaging over two energies: 0 and $\varepsilon = 2$ with equal probabilities, for various values of λ : $\lambda = 3, 3.3, 4, 6, 10$ and $+\infty$. The top graph corresponds to the case $\varepsilon = 4.5$ and $\lambda = 10$.

4.2.3 Trinomial distribution: $\lambda = +\infty$.

We also briefly consider the trinomial distribution, taking for simplicity equal probabilities, i.e.

$$\varepsilon^\omega = \begin{cases} 0 & \text{Pr} = 1/3 \\ \frac{1}{2}\varepsilon & \text{Pr} = 1/3 \\ \varepsilon & \text{Pr} = 1/3 \end{cases}. \quad (4.59)$$

For hard-core bosons, $\lambda = +\infty$, equation (4.13) for the critical value of $\beta_c(\rho)$ takes the form:

$$\frac{1}{3} \left[\frac{\tanh \frac{1}{2}\beta(\mu - 1)}{\mu - 1} + \frac{\tanh \frac{1}{2}\beta(\mu - 1 - \frac{1}{2}\varepsilon)}{\mu - 1 - \frac{1}{2}\varepsilon} + \frac{\tanh \frac{1}{2}\beta(\mu - 1 - \varepsilon)}{\mu - 1 - \varepsilon} \right] = 1. \quad (4.60)$$

The density equation (4.14) now reads as

$$\rho = \frac{1}{2} + \frac{1}{6} \left(\tanh \frac{1}{2} \beta (\mu - 1) + \tanh \frac{1}{2} \beta (\mu - 1 - \frac{1}{2} \varepsilon) + \tanh \frac{1}{2} \beta (\mu - 1 - \varepsilon) \right). \quad (4.61)$$

Then by the same analysis as in Sect.4.2.1 one gets from (4.61):

$$\lim_{\beta \rightarrow \infty} \rho(\beta, \mu) = \begin{cases} 0 & \text{if } \mu < 1 \\ 1/6 & \text{if } \mu = 1 \\ 1/3 & \text{if } 1 < \mu < 1 + \varepsilon/2 \\ 1/2 & \text{if } \mu = 1 + \varepsilon/2 \\ 2/3 & \text{if } 1 + \varepsilon/2 < \mu < 1 + \varepsilon \\ 5/6 & \text{if } \mu = 1 + \varepsilon \\ 1 & \text{if } \mu > 1 + \varepsilon \end{cases} .$$

Other way around this can be also expressed as:

$$\lim_{\beta \rightarrow \infty} \mu(\beta, \rho) = \begin{cases} 1 & \text{if } 0 < \rho < 1/3; \\ 1 + \varepsilon/4 & \text{if } \rho = 1/3; \\ 1 + \varepsilon/2 & \text{if } 1/3 < \rho < 2/3; \\ 1 + 3\varepsilon/4 & \text{if } \rho = 2/3; \\ 1 + \varepsilon & \text{if } \rho > 2/3. \end{cases}$$

Again, similar to the reasoning in Sect.4.2.1, the inserting of $\mu = 1 + \varepsilon/4$ or $\mu = 1 + 3\varepsilon/4$ into the limiting equation (4.60) for $\beta \rightarrow +\infty$ yields the critical value of the random potential:

$$\varepsilon_{\text{cr}} = \frac{28}{9} . \quad (4.62)$$

Therefore, (similar to the Bernoulli case for $\rho = 1/2$) the condensation of hard-core bosons is absent at densities $\rho = 1/3$ and $\rho = 2/3$, if $\varepsilon \geq \varepsilon_{\text{cr}}$. This phenomenon of course persists for $\lambda < +\infty$ and there are similar suppressions of Bose condensation at $\rho = 4/3, 5/3$, etc., if ε is large enough.

4.2.4 Trinomial distribution: $\lambda < +\infty$.

For $\lambda < +\infty$ there is a similar enhancement of Bose condensation at $\rho = 1$ as for the Bernoulli distribution, but the effect is stronger. This can be seen in Figure 2. The explanation is similar to that in Remark 4.3, except now the lattice splits into 3 equal parts with energies 0, $\varepsilon/2$ and ε . Particles can jump from a singly-occupied site with energy ε to a singly-occupied site with energy 0 or $\varepsilon/2$, thus compensating for the energy penalty of λ due to double occupation.

By equation (4.14) for (4.59) we obtain that at $\rho = 1$, $\mu(\beta, \rho) \rightarrow 1 + \lambda + \varepsilon/2$ as $\beta \rightarrow +\infty$. The gap equation (4.60) then reduces to

$$\frac{1}{\lambda - \varepsilon/2} + \frac{1}{\lambda} + \frac{1}{\lambda + \varepsilon/2} = 1 .$$

We can solve it for ε provided $\lambda \geq 3$:

$$\varepsilon_{\text{cr}}(\lambda) = 2\lambda \sqrt{\frac{\lambda - 3}{\lambda - 1}} . \quad (4.63)$$

Thus, Bose condensation is absent, if $\lambda \geq 3$ and $\varepsilon \leq \varepsilon_{\text{cr}}(\lambda)$.

Figure 2 shows $\beta_c(\rho)$ for a fixed $\varepsilon = 10$ and for values of $\lambda \geq 3$. Then $\varepsilon \geq \varepsilon_{\text{cr}}(\lambda = 3, 4, 6)$, but $\varepsilon < \varepsilon_{\text{cr}}(\lambda = 8) = 13.52$, which excludes condensation at $\rho = 1$ in the latter case.

Figure 2: β_c as a function of the density ρ in the case of a trinomial distribution with width $\varepsilon = 10$ for $\lambda = 3, 4, 6$ and 8.

4.2.5 General discrete distribution.

The same phenomena persist for higher numbers of random potential energy values, but the critical value $\varepsilon_{cr}(\lambda)$ becomes rapidly very large. Figure 3 shows the case of a distribution with equal probabilities $\text{Pr} = 1/10$ at 10 equidistant values of ε^ω (with maximal value $\varepsilon = 10$) for $\lambda = 8$. Clearly, condensation is suppressed at $\rho = 1/10, \dots, 9/10$ and $\rho = 1, 2$ but not at corresponding fractional values above 1, cf. Figure 2.

Figure 3: β_c as a function of the density ρ in the case of averaging over 10 energy values with width $\varepsilon = 10$ for $\lambda = 8$.

4.3 Continuous distribution

4.3.1 The case $\lambda = +\infty$.

Consider a random potential with *homogeneous* distribution between 0 and ε . In case $\lambda = +\infty$ the equations (4.13) and (4.14) become

$$\frac{1}{\varepsilon} \int_0^\varepsilon \frac{\tanh \frac{1}{2}\beta(\mu - 1 - x)}{\mu - 1 - x} dx = 1 \quad (4.64)$$

and

$$\frac{1}{\varepsilon} \int_0^\varepsilon \tanh \frac{1}{2}\beta(\mu - 1 - x) dx = 2\rho - 1 . \quad (4.65)$$

The latter has sense only for $0 \leq \rho \leq 1$ and can be solved exactly for μ :

$$\frac{2}{\beta\varepsilon} \ln \frac{e^{\beta(\mu-1)/2} + e^{-\beta(\mu-1)/2}}{e^{\beta(\mu-1-\varepsilon)/2} + e^{-\beta(\mu-1-\varepsilon)/2}} = 2\rho - 1 ,$$

and hence

$$\mu(\beta, \rho) = 1 + \frac{1}{2}\varepsilon + \frac{1}{\beta} \ln \frac{\sinh \frac{1}{2}\beta\rho\varepsilon}{\sinh \frac{1}{2}\beta(1-\rho)\varepsilon} . \quad (4.66)$$

As $\beta \rightarrow +\infty$, the expression (4.66) takes the form

$$\lim_{\beta \rightarrow +\infty} \mu(\beta, \rho) := \bar{\mu}(\rho) = 1 + \varepsilon\rho , \quad 0 < \rho < 1 , \quad (4.67)$$

whereas $\bar{\mu}(\rho = 0) \in (-\infty, 1]$ and $\bar{\mu}(\rho = 1) \in [1 + \varepsilon, +\infty)$ for extreme values of density, i.e., the inverse function is

$$\bar{\rho}(\mu) = \begin{cases} 0 & \mu \leq 1 \\ (\mu - 1)/\varepsilon & 1 < \mu < 1 + \varepsilon \\ 1 & 1 + \varepsilon \leq \mu . \end{cases} \quad (4.68)$$

Then by (4.64) and (4.68) we obtain for $\rho = 1$ in the limit $\beta \rightarrow +\infty$:

$$1 = \frac{1}{\varepsilon} \int_0^\varepsilon \frac{1}{\mu - 1 - x} dx ,$$

or we get explicitly the value of the chemical potential

$$\bar{\mu}(\rho = 1) = 1 + \frac{\varepsilon}{1 - e^{-\varepsilon}} > 1 + \varepsilon ,$$

and similarly

$$\bar{\mu}(\rho = 0) = 1 - \frac{\varepsilon e^{-\varepsilon}}{1 - e^{-\varepsilon}} < 1 .$$

Hence, for hard-core bosons the critical $\beta_c(\rho)$ is infinite at extreme densities $\rho = 0, 1$ for *any* value $\varepsilon > 0$ of the uniform continuous distribution.

If $0 < \rho < 1$, then solution of the equation (4.65) in the limit $\beta \rightarrow +\infty$ is (4.67), whereas the integral in (4.64) diverges. Therefore, if the critical $\beta_c(0 < \rho < 1)$ exist, it must be bounded. Moreover, since $(\tanh u)/u \leq 1$, by (4.64) we get for it a bound from below: $2 < \beta_c(0 < \rho < 1)$.

To prove the existence and uniqueness of $\beta_c(0 < \rho < 1)$ consider first (4.65) for $\rho \leq \frac{1}{2}$. Then by virtue of (4.66) for *any* finite β the solution $\mu(\beta, \rho)$ increases from $-\infty$ to $1 + \varepsilon/2$ when ρ

changes from 0 to $1/2$. For this variation of chemical potential the integral in the left-hand side of (4.64) increases monotonously from 0 to its *maximal* value given by

$$I(\beta, \mu = 1 + \varepsilon/2) = \frac{1}{\varepsilon} \int_0^\varepsilon \frac{\tanh \frac{1}{2}\beta(x - \varepsilon/2)}{x - \varepsilon/2} dx . \quad (4.69)$$

Indeed,

$$\partial_\mu I(\beta, \mu) = \frac{1}{\varepsilon} \left(\frac{\tanh \frac{1}{2}\beta(\mu - 1)}{\mu - 1} - \frac{\tanh \frac{1}{2}\beta(\mu - 1 - \varepsilon)}{\mu - 1 - \varepsilon} \right) \geq 0$$

for $\mu \leq 1 + \varepsilon/2$. The integral in (4.69) is obviously an increasing function of β . So, there exist $\beta_0 > 2$ such that the maximal value of integral $I(\beta_0, \mu = 1 + \varepsilon/2) \geq 1$. Hence, for any $\beta \geq \beta_0$ there is a *unique* density $0 < \bar{\rho}(\beta) \leq 1/2$ such that

$$I(\beta, \mu(\beta, \bar{\rho}(\beta))) = 1 . \quad (4.70)$$

Notice that by (4.66) $\mu(\beta, \rho)$ is increasing of the both arguments: β and $0 < \rho \leq 1/2$. Hence, to satisfy (4.70) $\bar{\rho}(\beta)$ must be decreasing function of β , i.e., the *inverse* function $\beta_c = \beta_c(\rho)$ is also a decreasing with $\lim_{\rho \rightarrow 0} \beta_c(\rho) = +\infty$ and $\lim_{\rho \rightarrow 1/2} \beta_c(\rho) \geq \beta_0$.

Similar arguments are valid for $1/2 \leq \rho < 1$. Whereas $\mu(\beta, \rho)$ is still increasing function of ρ , the integral $I(\beta, \mu)$ now decreases with μ from its maximal value (4.69) to 0. Therefore, $\beta_c = \beta_c(\rho)$ is a monotonously increasing function of ρ with $\lim_{\rho \rightarrow 1/2} \beta_c(\rho) \geq \beta_0$ and $\lim_{\rho \rightarrow 1} \beta_c(\rho) = +\infty$, i.e. with a minimum at $\rho = 1/2$ as we have seen for discrete distributions and hard-core bosons.

4.3.2 The case of large $\lambda < +\infty$.

By virtue of equations (4.5) and (4.6), for $\lambda < +\infty$, the Bose condensate is still suppressed at $\rho = k$.

The analysis is very similar to the case $\varepsilon = 0$. In the limit $\beta \rightarrow +\infty$ by (4.6) the density tends to ($k = 0, 1, \dots$)

$$\rho(\mu, \beta) \rightarrow \begin{cases} 0 & \text{if } \mu < 1 \\ k + \frac{1}{\varepsilon}(\mu - 1 - 2k\lambda) & \text{if } 1 + 2k\lambda < \mu < 1 + 2k\lambda + \varepsilon \\ k + 1 & \text{if } 1 + 2k\lambda + \varepsilon < \mu < 1 + 2(k+1)\lambda. \end{cases}$$

(To see this note that if $1 + 2k\lambda < \mu < 1 + 2k\lambda + \varepsilon$ then the term $e^{-\beta h_{k+1}}$ dominates for $x < \mu - 1 - 2k\lambda$ and the term $e^{-\beta h_k}$ dominates for $x > \mu - 1 - 2k\lambda$.) Clearly, if $0 < \rho < 1$ then for solution of (4.6) one gets as above: $\mu(\beta, \rho) \rightarrow 1 + \rho\varepsilon$ when $\beta \rightarrow +\infty$. If $\rho = 1$, we need to approximate (4.6) more carefully:

$$\begin{aligned} 1 &\approx \frac{1}{\varepsilon} \int_0^\varepsilon \frac{e^{\beta(\mu-1-x)} + 2e^{2\beta(\mu-1-x-\lambda)}}{1 + e^{\beta(\mu-1-x)} + e^{2\beta(\mu-1-x-\lambda)}} dx \\ &\approx \frac{1}{\varepsilon} \int_0^\varepsilon [1 + e^{-\beta(1+x+2\lambda-\mu)} - e^{-\beta(\mu-1-x)}] dx. \end{aligned}$$

Working out the integral, we find that $\mu(\beta, \rho = 1) \rightarrow 1 + \lambda + \frac{1}{2}\varepsilon$ as $\beta \rightarrow +\infty$. More generally, if $\rho = k$, $\mu(\beta, \rho = k) \rightarrow 1 + (2k - 1)\lambda + \frac{1}{2}\varepsilon$. For large β , the gap equation (4.5) becomes

$$\frac{1}{\varepsilon} \int_0^\varepsilon \left\{ \frac{k}{\mu - 1 - 2(k-1)\lambda - x} + \frac{k+1}{1 + 2k\lambda + x + 2\lambda - \mu} \right\} dx = 1.$$

Inserting $\mu = 1 + (2k - 1)\lambda + \frac{1}{2}\varepsilon$ we obtain that

$$\frac{1}{\varepsilon} \int_0^\varepsilon \left\{ \frac{k}{\lambda + \frac{1}{2}\varepsilon - x} + \frac{k+1}{\lambda - \frac{1}{2}\varepsilon + x} \right\} dx = 1.$$

This gives for the critical values of repulsion:

$$\lambda_{c,k}(\varepsilon) = \frac{1}{2}\varepsilon \frac{e^{\varepsilon/(2k+1)} + 1}{e^{\varepsilon/(2k+1)} - 1}. \quad (4.71)$$

It is easy to see that this is larger than for non-random case $\lambda_{c,k}(0) = 2k + 1$ and agrees with the value mentioned above at $\varepsilon = 0$, see Sect.4.2.2 .

Figure 3 shows the phase diagram for $\lambda = 10$ with $\varepsilon = 3$, taking an average over a uniform distribution corresponding to 10 equidistant random values of ε^ω in the interval $[0, 3]$. It shows that this already approximates the continuous case quite well.

Figure 4: β_c as a function of the density ρ in the case of a near-continuous distribution: averaging over 10 energy values with width $\varepsilon = 3$ for $\lambda = 10$. The lower graph is the case without randomness.

4.3.3 The case of small $\lambda > 0$.

We finally consider the case of small λ . Figure 4 shows that, in contradistinction to the case $\lambda = 0$, for small λ the critical $\beta_c(\lambda, \varepsilon) > \beta_c(\lambda = 0, \varepsilon = 0)$, i.e. it is *larger* than that at $\varepsilon = 0$!

This can be understood as follows. Whereas in the free case $\lambda = 0$, we must have $\mu < 0$, when $\lambda > 0$, this is no longer so. In the limit $\lambda \rightarrow 0$, we can replace $e^{-\beta h_n(\mu, \lambda)}$ in the expression (4.4) for $\tilde{p}''(\beta, \mu, \lambda; 0)$ occurring in the gap equation (4.5) by $e^{\beta(\mu-1)}$. Replacing also $h_{n-1} - h_n$ (see (4.2)) by $\mu - 1$ the series (4.4) can be summed and we obtain for (4.5):

$$\frac{1}{\varepsilon} \int_0^\varepsilon \frac{1}{1+x-\mu} dx = 1 .$$

If $\varepsilon = 0$ this leads to the free gas critical value $\mu = 0$, but for $\varepsilon > 0$ we obtain

$$\mu = \frac{e^\varepsilon - 1 - \varepsilon}{e^\varepsilon - 1} > 0 . \quad (4.72)$$

Figure 5: β_c as a function of the density ρ in the case of averaging over two energies and width $\varepsilon = 2$ for small $\lambda = 0.1$. For comparison, the lower graph shows the case without randomness.

Similarly, the density equation (4.6) now reads as

$$\frac{1}{\varepsilon} \int_0^\varepsilon \frac{1}{e^{\beta(1-\mu+x)} - 1} dx = \rho . \quad (4.73)$$

By (4.72) we can approximate for small ε μ by $\mu \approx \varepsilon/2$ and inserting it in (4.73) we find

$$\frac{1}{\varepsilon} \int_0^\varepsilon \frac{1}{e^{\beta(1-\varepsilon/2+x)} - 1} dx = \rho . \quad (4.74)$$

By convexity of the function $(e^{\beta(1+x)} - 1)^{-1}$, we conclude for solution of the equation (4.74) that

$$\beta_c(\rho, \varepsilon) > \beta_c(\rho, 0) = \ln \left(1 + \frac{1}{\rho} \right) .$$

Notice that this argument also applies in the case of a discrete distribution, see Figure 5.

5 Conclusion

We conclude by few remarks concerning our results and open problems. Summarizing the most striking observations about the model considered in this paper, we have seen that at large values of the on-site repulsion with a discrete distribution of the random single-site particle potential, the disorder causes a suppression of Bose-Einstein condensation at fractional values of the density. On the other hand, the suppression of Bose-Einstein condensation at integer values of the density observed in the absence of disorder is lifted. For continuous distributions we found that the critical temperature decreases with increasing disorder for non-integer densities.

We have concentrated here on the case of uniformly distributed random external potential. Nonuniform distributions as well as a random on-site interaction may also be of interest

and give rise to new phenomena. Of course, all our results concern the infinite-range-hopping model. It would be of considerable interest to extend our results to the short-range hopping model.
