ABSTRACT

unitary property $GG^{\dagger} = \tilde{\Omega}^2 I$ (where $\tilde{\Omega}^2$ is a scalar). unitarity in the cases of coexisting superconducting and density unitary of Helium Three, however, this property of the Green's wave systems. experimentally; and we explore some of the consequences of are particularly easy to treat both theoretically and satisfy this pseudo-unitary constraint. is not automatic. By analogy with this latter case we define superconductivity, for example, where it possesses the pseudogeneralized Green's function G is well-known in the case of Green's function in an algebraically explicit way. many-fermion systems characterized by their dynamical algebras We discuss a class of mean field hamiltonians for interacting such systems systems (or the states of such systems) as those which one can easily derive the finite temperature Such constrained systems In the case function

function $G_{i,j}$ is introduced as a thermodynamic expectation approach in the present note. In the many body case, the Green's body physics, and it is unnecessary to reiterate the value of this method of Green's functions is standard in field theory and

$$G_{i,j}(x\tau,x^{\dagger}\tau^{\dagger}) = -\langle T_{\tau}(\psi_{i}(x\tau)\psi_{j}(x^{\dagger}\tau^{\dagger}))\rangle$$
ere $\langle Q \rangle = (\text{tr } e^{-\beta\kappa}Q)/(\text{tr } e^{-\beta\kappa})$ $(\beta = (k_{B}T)^{-1})$

for any operator Q and hamiltonian $K = H - \mu N$.

We assume that we are dealing with fermion field operators

$$\psi_{i}(x\tau) = e^{K\tau} \psi_{i}(x) e^{-K\tau} \qquad (A = 1)$$

$$\tilde{\psi}_{i}(x\tau) = e^{K\tau} \psi_{i}(x) e^{-K\tau} \qquad (i = 1, 2, ..., n)$$

Here x,x' are the spatial co-ordinates, and T_{τ} is a τ -ordering operator Heisenberg evolution. We shall work in the Fourier transformed case, for the parameter τ , which is in general complex; in this latter case that $\psi_i(x\tau) \neq \psi_i(x\tau)^+$. For T = it (t = time) this gives the usual

$$\psi_{\mathbf{i}}(\mathbf{x}) = VOL^{-\frac{1}{2}} \sum_{\mathbf{k}} A_{\mathbf{i}}(\mathbf{k}) e^{i\mathbf{k}\mathbf{x}}$$

when the Green's function becomes

$$G_{i,j}(k\tau) = -\langle T_{\tau}(A_{i}(k\tau)A_{j}(k0))\rangle$$

Using the periodicity of this latter function, period 2β , we may write

$$G_{ij}(k\omega) = \int_0^\beta G_{ij}(k\tau)e^{i\tau\omega}d\tau.$$

assume that our hamiltonian may be written It is straightforward to evaluate this [For Fermi statistics ω takes values ω n in the mean-field case, where we = $(2n+1)\pi/\beta$, n = 1,2,3,...]

$$K = \sum_{k} K(k)$$

 $K = \sum_{i,j} m_{i,j}(k) A_{i}^{+}(k) A_{i}(k)$.

The fermion operators $A_{f i}(k)$ satisfy the standard anticommutation relations

$$\{A_{i}(k), A_{i}^{+}(k')\} = \delta_{i,j} \delta_{kk'}.$$

Writing $X_{...}(k) \equiv A_{i}^{+}(k)A_{...}(k)$, (i,j,=1,2,...,n)

these anticommution relations lead to the commutation relations

$$[X_{i,j},X_{k,\ell}] = \delta_{i,k}X_{i,\ell} - \delta_{i,\ell}X_{k,j}$$

is an element of a subalgebra of $igoplus_k g \ell(n)_{(k)}$. [If the complex (suppressing explicit k-dependence) which shows that our hamiltonian

the $X_{i,j}$, we may readily obtain g&(n).] Since the $\{A_i\}$ form a first rank contravariant tensor under case - then the dynamical algebra is a subalgebra of u(n) rather than coefficients $m_{i,j}(k)$ are such that each K(k) is hermitian – the usual

$$A_{\mathbf{i}}(\mathbf{k} \mathbf{z}) = \sum_{\mathbf{j}} (e^{-m\tau})_{\mathbf{i},\mathbf{j}} A_{\mathbf{j}}(\mathbf{k}) = \sum_{\mathbf{j}} A_{\mathbf{i},\mathbf{j}}(\mathbf{k}\tau) A_{\mathbf{j}}(\mathbf{k})$$

function $G_{i,j}(k\omega)$ A standard manipulation [1] then gives for the transformed Green's where m is the matrix $(m_{i,j}(k))$, and $\Lambda = e^{-m\tau}$.

$$G(k\omega) = (i\omega I - m)^{-1}.$$

As mentioned, the matrix m is hermitian. If m is also pseudo-unitary, that is

$$m^2 = \Omega_0^2 I$$

some scalar Ω_0 , then $G(k\omega)$ is explicitly invertible

$$G(k\omega) = (-i\omega I - m)/\Omega^2$$

where

$$\Omega^2 = \Omega_0^2 + \omega^2$$

In this case G is also pseudo-unitary,

$$GG^{\dagger} = (\Omega^{-2})I.$$

systems of physical interest - as we now illustrate - and makes their Although this condition is highly restrictive, it is satisfied by some treatment that much simpler, both theoretically and experimentally. These are the systems which we refer to as unitary in this note.

generating algebra of the system with hamiltonian K.] For a rank-l obtained by looking at the dynamical algebra g of the system. isomorphic to g, we refer to g as the dynamical or spectrum An idea of just how restrictive this unitary condition is may be if the hamiltonian K is an element of $igoplus_k g_k$, with each

algebra g there will be invariants $I_r = tr m^r (r = 1, 2, ...)$ associated with the matrix m of the hamiltonian K(k); at most l of these will be independent. For a unitary system this number is reduced to at most two invariants, corresponding to tr m and tr m² = $n\Omega_0^2$; in the traceless (semi-simple) case, there is only one invariant. Thus su(1) is automatically unitary - the case of superconductivity; but so(5)being of rank 2, unitarity imposes one condition - and this is the case for superfluid helium three (from which situation we have borrowed the nomenclature [2]). We describe the helium three case now [3]. After a Hartree-Fock linearisation, the effective hamiltonian for an interacting fermion fluid with pairing in opposite momentum (but not necessarily opposite spin) states is given by $K = \sum_{k} K(k)$, where

$$K(k) = \sum_{\alpha} \xi_{k} (a_{k\alpha}^{\dagger} a_{k\alpha} + a_{-k\alpha}^{\dagger} a_{-k\alpha}) + (\sum_{\alpha,\beta} V(k,\alpha,\beta) a_{k\alpha}^{\dagger} a_{-k\beta}^{\dagger} + h.c.)$$

Choosing a basis of fermion operators $\{A_i^{(k)}\}$,

$$(A_1^{(k)}, A_2^{(k)}, A_3^{(k)}, A_4^{(k)}) = (a_{k\uparrow}, a_{k\downarrow}, a_{-k\downarrow}, a_{-k\uparrow})$$

we may write the matrix m in the spin-triplet case as

$$\mathbf{m} = \begin{bmatrix} \mathbf{E} & \mathbf{V} \\ \mathbf{V}^{+} & -\mathbf{E} \end{bmatrix}$$

where E = $\xi \tau_0$ (with $\xi_k \equiv \xi_k - \mu$; we suppress the momentum index) and $V = \underline{d} \cdot \underline{\tau}$, with $d_1 = \frac{1}{2} (V_{\downarrow \downarrow} - V_{\uparrow \uparrow})$, $d_2 = -\frac{1}{2} i (V_{\uparrow \uparrow} + V_{\downarrow \downarrow})$, $d_3 = \frac{1}{2} (V_{\uparrow \downarrow} + V_{\downarrow \uparrow})$. The unitary condition $m^2 = (\Omega^2 - \omega^2)I$ leads to

$$[\mathbf{v},\mathbf{v}^{+}]=0$$

which is
$$\underline{d} \times \underline{d}^* = 0$$

a form given by, for example, Leggett.

For such unitary states the 4 × 4 Green's function is of course immediate, with $\Omega^2 = \omega^2 + \xi^2 + |\mathbf{d}|^2$.

This exemplifies a characteristic feature of unitary systems; there is a single degenerate energy gap, in the helium three case given by

algebra we would expect & "gaps". This gives a useful experimental for the hamiltonian for this model as Sooryakumar and Klein on a system of coexisting charge-density waves criterion, which we now illustrate by reference to the experiment of $|\mathsf{d}|^2$. For a system described by a rank-2 spectrum generating Lie superconductivity [4]. We may write the representative matrix m

$$\mathbf{m} = \begin{bmatrix} \xi & -\Delta & \gamma & -\Delta - Q \\ -\Delta & -\xi & -\Delta & \gamma & -\Delta - Q \\ \gamma & -\Delta & -\xi & -\Delta & -\gamma \\ -\Delta & -\Delta & -\gamma & -\Delta & -\xi \end{bmatrix}$$

in a basis

$$(A_{1}(k), A_{2}(k), A_{3}(k), A_{4}(k)) = (a_{k1}, a_{-k1}, a_{-k1}, a_{-k1}).$$

Here $\xi' \equiv \xi(k-Q) \equiv \xi(k-Q) - \mu$, k = k - Q, where Q is the characteristic Δ_Q and Δ_{-Q} are so-called anomalous terms, appearing in the hamiltonian superconductivity and CDW are given by Δ and γ respectively, while wave vector for CDW propagation. The couplings for conventional

$$-\Delta_{Q} a_{k}^{+} + a_{k}^{+} - \Delta_{Q} a_{k}^{-} a_{-k}^{+} + h.c.$$

known as the nesting condition. As the experiment referred to shows neglecting the anomalous terms, this means that the nesting condition the presence of two energy gaps, below the appropriate lowest condition forces $\Delta_Q = \Delta_{-Q} = 0$, and $\xi + \xi' = 0$. This last condition is The dynamical algebra here is su(4) [5], which is rank 3. The unitary Therefore at least one of the given conditions must fail. In a model transition temperature, we can assert that the system is not unitary.

hermitian representation. Unitary states occur when all there is only generating algebra is compact, and so has a finite-dimensional For the many fermion systems we have considered, the spectrum

inversion in the mean field case. temperature In that case the system exhibits a single energy gap, and the finiteone invariant associated with the matrix representing the hamiltonian. Green's function is immediately obtainable without matrix
